In Parallel Flash Mode, both flashes are read with the same starting address of 3/4 (as programmed in the instruction/operand in the sequence) bytes in size. This address is derived from SFADR [24:1] or SFADR [31:1] as given in the table above. The LSB of the SFADR field is used to select the appropriate bits of both flash devices to combine the byte corresponding to the selected address.

43.3.4 AHB Bus Register Memory Map Descriptions

This chapter contains definitions of registers in the AMBA address space.

43.3.4.1 AHB Bus Access Considerations

It has to be noted that all logic in the QuadSPI module implementing the AHB Bus access is designed to read the content of an external serial flash device. Therefore the following restrictions apply to the QuadSPI module with respect to accesses to the AHB bus:

- Any write access is answered with the ERROR condition according to the AMBA AHB Specification. No write occurs.
- Any AHB Command resulting in the assertion of the QSPI_FR[ABSEF] flag is answered with the ERROR condition according to the AMBA_AHB specification. The resulting AHB Command is ignored.

- AHB Bus access types fully supported are NONSEQ and BUSY.
- AHB access type SEQ is treated in the same way like NONSEQ. Refer to the AMBA AHB Specification for further details.

43.3.4.2 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A

Starting with address `QSPI_AMBA_BASE` the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address `0x0` corresponds to bus address `QSPI_AMBA_BASE` with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 43-14](#) and for 64 bit read access the byte ordering is given in [Table 43-18](#).

Table 43-7. Memory Mapped Individual Flash Mode - Flash A Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
<code>QSPI_AMBA_BASE + 0x00</code>	<code>QSPI_AMBA_BASE + 0x00</code>	<code>0x00_0000 to 0x00_0003</code>	A1
<code>QSPI_AMBA_BASE + 0x04</code>		<code>0x00_0004 to 0x00_0007</code>	
...		...	
<code>TOP_ADDR_MEMA1 - 0x08</code>	<code>TOP_ADDR_MEMA1 - 0x08</code>	<code>(TOP_ADDR_MEMA1 - 0x08) to (TOP_ADDR_MEMA1 - 0x04 - 0x01)</code>	
<code>TOP_ADDR_MEMA1 - 0x04</code>		<code>(TOP_ADDR_MEMA1 - 0x04) to (TOP_ADDR_MEMA1 - 0x01)</code>	
<code>TOP_ADDR_MEMA1 + 0x00</code>	<code>TOP_ADDR_MEMA1 + 0x00_0000</code>	<code>0x00_0000 to 0x00_0003</code>	A2
<code>TOP_ADDR_MEMA1 + 0x04</code>		<code>0x00_0004 to 0x00_0007</code>	
.....		...	
<code>TOP_ADDR_MEMA2 - 0x08</code>	<code>TOP_ADDR_MEMA2 - 0x08</code>	<code>(TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMA2 - 0x04 - 0x01)</code>	
<code>TOP_ADDR_MEMA2 - 0x04</code>		<code>(TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMA2 - 0x01)</code>	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

43.3.4.3 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B

Starting with address `TOP_ADDR_MEMA2` the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address `0x0` corresponds to bus address `TOP_ADDR_MEMA2` with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 43-14](#) and for 64 bit read access the byte ordering is given in [Table 43-18](#).

Table 43-8. Memory Mapped Individual Flash Mode - Flash B Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
<code>TOP_ADDR_MEMA2 + 0x00</code>	<code>TOP_ADDR_MEMA2 + 0x00</code>	<code>0x00_0000 to 0x00_0003</code>	B1
<code>TOP_ADDR_MEMA2 + 0x04</code>		<code>0x00_0004 to 0x00_0007</code>	
...		...	
<code>TOP_ADDR_MEMB1 - 0x08</code>	<code>TOP_ADDR_MEMB1 - 0x08</code>	<code>(TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x04 - 0x01)</code>	
<code>TOP_ADDR_MEMB1 - 0x04</code>		<code>(TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x01)</code>	
<code>TOP_ADDR_MEMB1 + 0x00</code>	<code>TOP_ADDR_MEMB1 + 0x00_0000</code>	<code>0x00_0000 to 0x00_0003</code>	B2
<code>TOP_ADDR_MEMB1 + 0x04</code>		<code>0x00_0004 to 0x00_0007</code>	
.....		...	
<code>TOP_ADDR_MEMB2 - 0x08</code>	<code>TOP_ADDR_MEMA2 - 0x08</code>	<code>(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x08) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x04 - 0x01)</code>	
<code>TOP_ADDR_MEMB2 - 0x04</code>		<code>(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x04) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x01)</code>	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

43.3.4.4 Parallel Flash Mode

Any of the AHB flexible-buffers can be configured to work in parallel flash mode by programming the QSPI_BFGENCR[PAR_EN] bit to '1'. When parallel mode is set, Flash A1 is paired with Flash B1 and Flash A2 is paired with Flash B2. In parallel mode, software should ensure that the size of Flash A1(A2) is equal to the size of Flash B1(B2).

Reads from any even AHB bus address provides bits [7:4] of both serial flash devices and reads from any odd AHB bus address provides bits [3:0] of both flash devices. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 43-16](#) and for 64 bit read access the byte ordering is given in [Table 43-18](#).

Table 43-9. Memory Mapped Parallel Flash Mode Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash A Byte Address	Serial Flash B Byte Address
QSPI_AMBA_BASE + 0x0000_0000	QSPI_AMBA_BASE + 0x00 For details, please refer to Parallel mode and Dual Die Flashes .	0x00_0000	0x00_0000
QSPI_AMBA_BASE + 0x0000_0004		-	-
		0x00_0001	0x00_0001
		0x00_0002	0x00_0002
		-	-
		0x00_0003	0x00_0003
QSPI_AMBA_BASE + 0x0000_0008	QSPI_AMBA_BASE + 0x08	0x00_0004	0x00_0004
		-	-
		0x00_0005	0x00_0005
QSPI_AMBA_BASE + 0x0000_000C		0x00_0006	0x00_0006
		-	-
		0x00_0007	0x00_0007
...
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMB2 - 0x08	$(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2$	$(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2$
TOP_ADDR_MEMB2 - 0x04		$(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x04)/2 + 0x01$	$(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x04)/2 + 0x01$

The available address range covers 27 address bits, corresponding to 128 MB per flash device. The usable space depends from the size of the external serial flash devices. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

43.4 Interrupt Signals

The interrupt request lines of the QuadSPI module are mapped to the internal flags according to the following table.

Table 43-10. Assignment of Interrupt Request Lines

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
ipi_int_tfff	TBFF	TX Buffer Fill
ipi_int_tcf	TFF	Peripheral Command Transaction Finished
ipi_int_rdfd	RBDF	RX Buffer Drain
ipi_int_overrun		Buffer Overflow/Underrun Error Logical OR from:
	RBOF	RX Buffer Overrun
	TBUF	TX Buffer Underrun
	ABOF	AHB Buffer Overflow
ipi_int_cerr		Serial Flash Command Error Logical OR from:
	IPAEF	Peripheral access while AHB busy Error
	IPIEF	Peripheral Command could not be triggered Error
	IPGEF	Peripheral access while AHB Grant Error
ipi_int_ored	IUEF	Peripheral Command Usage Error
	DLPFF, TBFF, TFF, ILLINE, RBDF, RBOF, TBUF, ABSEF, ABOF, IPAEF, IPIEF, IPGEF, IUEF	Logical OR from all the QSPI_FR flags mentioned

43.5 Functional Description

This section provides the functional information of the QuadSPI module.

43.5.1 Serial Flash Access Schemes

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to one single or two external serial flash devices, each with up to 4 bidirectional data lines. Depending from the serial flash devices attached to the QuadSPI module the following access schemes are possible:

Table 43-11. Access Schemes for Serial Flash Data Access

Access Scheme	One Flash Device on Port A	One Flash Device on Port B	Two identical Flash Devices connected on Port A and Port B
Individual Flash Mode: Access to Flash A	Yes	N/a	Yes
Individual Flash Mode: Access to Flash B	N/a	Yes	Yes
Parallel Flash Mode: Read from Flash A and Flash B	N/a	N/a	Yes

Note

If two flash devices are accessed in Parallel Flash Mode, they are accessed with identical control signals. Special alignment on per-flash basis is **not** possible. It is within the responsibility of the application to ensure that the identical signals are applicable to both flash devices.

In Parallel Flash Mode, both external serial flash devices appear logically as one single memory doubled in size with respect to one individual flash device.

If two different flash devices are attached, they can be operated only in Individual Flash Mode.

In the Parallel Flash Mode, only data read commands are supported. Any other IP Command will result in an error condition signaled by the assertion of the QSPI_FR[IUEF] flag and any other AHB Command will result in the assertion of the QSPI_FR[ABSEF] flag.

In the Individual Flash Mode, all supported commands are available.

Unless explicitly noted, all the following descriptions relate to the Individual Flash Mode.

43.5.2 Modes of Operation

Refer to [QuadSPI Modes of Operation](#) for an overview over the possible operational modes of the QuadSPI block.

- Normal Mode can be used for write or read accesses to an external serial flash device.

- Serial Flash Write: Data can be programmed into the flash via the IP interface only. Refer to [Flash Programming](#) for further details.
- Serial Flash Read: Read the contents of the serial flash device. Two separate read channels are available via RX Buffer and AHB Buffer, see [Flash Read](#).
- Stop Mode: The mode is used for power management. When a request is made to enter Stop Mode, the QuadSPI block acknowledges the request and completes the SFM Command in progress, then the system clocks to the QuadSPI block may be shut off
- Module Disable Mode: The mode is used for power management. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in Module Disable Mode. The module enters the mode by setting QSPI_MCR[MDIS].

43.5.3 Normal Mode

This mode is used to allow communication with an external serial flash device. Compared to the standard SPI protocol, this communication method uses up to 4 bidirectional data lines operating at high data rates. The communication to the external serial flash device consists of an instruction code and optional address, mode, dummy and data transfers. The flexible programmable core engine described below is immune to a wide variety of command/protocol differences in the serial flash devices provided by various flash vendors.

43.5.3.1 Programmable Sequence Engine

The core of the QuadSPI module is a programmable sequence engine that works on "instruction-operand" pairs. The core controller executes each programmed instruction sequentially. The complete list of instructions and the corresponding operands is given in the following table.

Table 43-12. Instruction set

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
CMD	6'd1	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads	8 bit command value	Provide the serial flash with operand on the number of pads specified

Table continues on the next page...

Table 43-12. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
ADDR	6'd2	2'd2 - Four pads	Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of SFAR in case of IPS initiated transactions .
DUMMY	6'd3		Number of dummy clock cycles (should be <= 64 cycles)	Provide the serial flash with dummy cycles as per the operand. The PAD information defines the number of pads in input mode. (for example, one pad implies that pad 1 is not driven, rest all are driven)
MODE	6'd4		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified
MODE2	6'd5	N=2'd{0,1}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads ¹ specified
MODE4	6'd6	N=2'd{0,1,2}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads ² specified
READ	6'd7	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Read data size in bytes (for AHB transactions, the user's application should ensure that data size is a multiple of 8 bytes)	Read data from flash on the number of pads specified. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions.
WRITE			6'd8	Write data size in bytes
JMP_ON_CS	6'd9	NA	Instruction number	Every time the CS is deasserted, jump to the instruction pointed to by the operand. This instruction allows the programmer to specify the behavior of the controller when a new read transaction is initiated following a CS deassertion.
ADDR_DDR	6'd10	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified at each clock edge of serial flash clock. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of QSPI_SFAR in case of IPS initiated transactions .
MODE_DDR			6'd11	8 bit mode value
MODE2_DDR	6'd12	N=2'd{0}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads specified at each clock edge of serial flash ³
MODE4_DDR	6'd13	N=2'd{0,1}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads specified at each clock edge of serial flash ⁴ .

Table continues on the next page...

Table 43-12. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
READ_DDR	6'd14	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Read data size in bytes (for AHB transactions, the user's application should ensure that data size is in multiple of 8 bytes)	Read data from flash on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions
WRITE_DDR	6'd15		Write data size in bytes	Write data on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the IDATSZ field of IP Configuration Register (QuadSPI_IPCR) register
DATA_LEARN ⁵	6'd16		8 bit Data learning pattern	Find the correct sampling point with the data learning pattern. When this instruction is encountered, the QSPI_SMPR[DDRSMP] values are ignored and the controller finds the correct sampling point on its own by sampling the data learning pattern. ⁶
STOP	8'd0	NA	NA	Stop execution; deassert CS

- For a one pad instruction, MODE2 will take 2 serial flash clock cycles on the flash interface.
- For a one pad instruction, MODE4 will take 4 serial flash clock cycles on the flash interface. For a 4 pad instruction, MODE4 will take 1 serial flash clock cycle on the flash interface.
- For a one pad instruction, MODE2_DDR will take 1 serial flash clock cycle on the flash interface.
- For a one pad instruction, MODE4_DDR will take 2 serial flash clock cycles on the flash interface. For a 4 pad instruction MODE4_DDR will take half a cycle on the serial flash interface.
- Data learning is not implemented on this chip.
- t is not recommended to have 0x00 or 0xFF as the data learning pattern.

A sequence of such instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence pre-programmed in the LUT is referred to by its index.

The programmable sequence engine allows the user to configure the QuadSPI module according to the serial flash connected on board. The flexible structure is easily adaptable to new command/protocol changes from different vendors.

43.5.3.2 Flexible AHB buffers

In order to reduce the latency of the reads for AHB masters, the data read from the serial flash is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 Bytes and maximum size being the size of the complete buffer instantiated. The size of buffer 0 is defined as being from 0 to QSPI_BUF0IND. The Size of buffer 1 is from QSPI_BUF0IND to

QSPI_BUF1IND, buffer2 is from QSPI_BUF1IND to QSPI_BUF2IND and buffer 3 is from QSPI_BUF2IND to the size of the complete buffer, which is given in the chip-specific QuadSPI information.

Each flexible AHB buffer is associated with the following

1. An AHB master. Optionally, buffer3 may be configured as an "all master" buffer by setting the QSPI_BUF3CR[ALLMST] bit. When buffer3 is configured in such a way, any access from a master not associated with any other buffer is routed to buffer3.
2. A datasize field representing the amount of data to be fetched from the flash on every "missed" access.

The master port number of every incoming request is checked and the data is returned/fetched into the corresponding associated buffer. Every "missed" access to the buffer causes the controller to clear the buffer and fetch QSPI_BUFxCR[ADATSZ] amount of data from the serial flash. As such, there is no benefit in configuring a buffer size of greater than ADATSZ, as the locations greater than ADATSZ will never be used. For any AHB access, the sequence pointed to by the QSPI_BFGENCR[SEQID] field is used for the flash transaction initiated. The data is returned to the master as soon as the requested amount is read from the serial flash. The controller however, continues to prefetch the rest of the data in anticipation of a next consecutive request. [Figure 43-4](#) shows the flexible AHB buffers.

The QSPI_BFGENCR[SEQID] field points to an index of the LUT. Refer to [Look-up Table](#) for details.

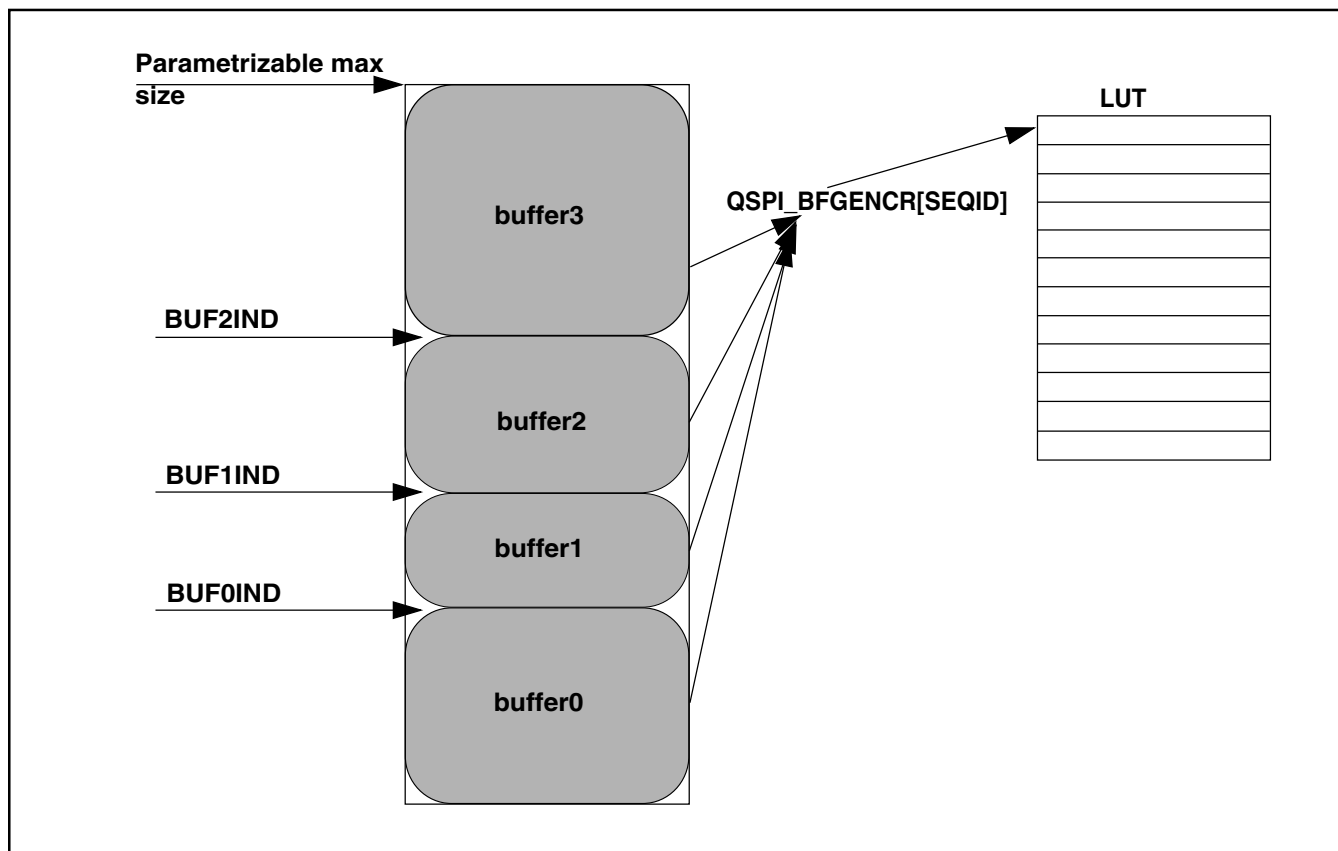

Figure 43-4. Flexible AHB Buffers

Buffer0 may optionally be configured to be associated with a high priority master by setting the QSPU_BUF0CR[HP_EN] bit. An access by a high priority master suspends any ongoing prefetch to any of the other buffers. The ongoing prefetch is suspended and the high priority master is serviced first. Once the high priority masters access completes, the suspended transaction is resumed (before any other AHB access is entertained). The status of the suspended buffer can be read from [Sequence Suspend Status Register \(QuadSPI_SPNDST\)](#).

43.5.3.3 Suspend-Abort Mechanism

Any low priority AHB access can be suspended by a high priority AHB master request. The ongoing transaction is suspended at 64 bit boundary. The suspended transaction is restarted after the high priority master is served and the high priority transaction including data prefetch is completed. While a transaction is in suspended state, it may be aborted if a transaction by the same suspended master is made to a location which is different from the location of the suspended transaction.

Any ongoing transaction is aborted if a request from the same master arrives for a location other than the location at which the transaction is going on. The abort can happen at any point of time.

43.5.3.4 Look-up Table

The Look-up-table or LUT consists of a number of pre-programmed sequences. Each sequence is basically a sequence of instruction-operand pairs which when executed sequentially generates a valid serial flash transaction. Each sequence can have a maximum of 8 instruction-operand pairs. The LUT can hold a maximum of sequences. The figure below shows the basic structure of the sequence in the LUT.

At reset, the index 0 of the look-up-table (LUT[0..3]) is programmed with a basic read sequence as given in [Table 43-13](#). After reset the complete LUT may be reprogrammed according to the device connected on board. In order to protect its contents during a code runover the LUT may be locked, after which a write to the LUT will not be successful until it has been unlocked again. The key for locking or unlocking the LUT is **0x5AF05AF0**. The process for locking and un-locking the LUT is as follows:

Locking the LUT

1. Write the key (**0x5AF05AF0**) in to the [LUT Key Register \(QuadSPI_LUTKEY\)](#).
2. Write 0b01 to the [LUT Lock Configuration Register \(QuadSPI_LCKCR\)](#). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register locks the LUT.

Unlocking the LUT

1. Write the key (**0x5AF05AF0**) into the [LUT Key Register \(QuadSPI_LUTKEY\)](#)
2. Write 0b10 to the [LUT Lock Configuration Register \(QuadSPI_LCKCR\)](#). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register unlocks the LUT.

The lock status of the LUT can be read from `QSPI_LCKCR[UNLOCK]` and `QSPI_LCKCR[LOCK]` bit.

Some example sequences are defined in [Example Sequences](#). The reset sequence at LUT index 0 is given in the following table.

Table 43-13. Reset sequence

Instruction	Pad	Operand	Comment
CMD	0x00	0x03	Read Data byte command on one pad
ADDR	0x00	0x18	24 Addr bits to be sent on one pad
READ	0x00	0x08	Read 64 bits
JMP_ON_CS	0x00	0x00	Jump to instruction 0 (CMD)

43.5.3.5 Issuing SFM Commands

Each access to the external device follows the same sequence:

1. The user must pre-populate the LUT with the serial flash command sequences that are required for the flash device being used.
2. The QuadSPI module starts executing the instructions in the sequence one by one. The transaction starts and the status bit QSPI_SR[BUSY] is set.
3. Communication with the external serial flash device is started and the transaction is executed.
4. When the transaction is finished (all transmit- and receive operations with the external serial flash device are finished) the status bit QSPI_SR[BUSY] is reset. In case of an IP Command the QSPI_FR[TFF] flag is asserted.

Further details are given in below in [Flash Programming](#) and [Flash Read](#).

You can trigger the processing of SFM commands in the QuadSPI module in one of the following ways:

- **Using IP commands**

For IP Commands the required components need to be written into the following registers:

- Write the serial flash address to be used by the instruction into QSPI_SFAR, refer to [Serial Flash Address Register \(QSPI_SFAR\)](#). For IP Commands not related to specific addresses, the base address of the related flash need to be programmed. For example, for an instruction which does not require an address (i.e. write enable instruction) the SFAR should be programmed with the base address of the memory the command is to be sent to.

- Write the sequence ID and data size details in the [IP Configuration Register \(QSPI_IPCR\)](#).
- Note that the write into the QSPI_IPCR[SEQID] field must be the last step of the sequence. It is possible to combine all fields of the QSPI_IPCR into one single write. Refer to [IP Configuration Register \(QSPI_IPCR\)](#) for details.

Note that there are some conditions where no IP Command is executed after writing the QSPI_IPCR[SEQID] field and the write operation itself is ignored. They are described in [Command Arbitration](#).

- **Using AHB commands**

Any AHB memory mapped access is routed to one of the buffers depending on the master port number of the request. If the access is a "miss", a new serial flash transaction is started. The transaction is based on the sequence pointed to by the BFGENCR[SEQID] field as described in [Flexible AHB buffers](#).

An AHB access is termed memory mapped when the access is to the memory mapped serial flashes, as described in [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A](#) and [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B](#).

Again the possible error conditions are described in [Command Arbitration](#).

43.5.3.6 Flash Programming

In all cases the memory sector to be written needs to be erased first. The programming sequence itself is then initiated in the following way:

1. Check that the TX Buffer is empty. If the QSPI_SR[TXEDA] bit is set then the TX Buffer must be cleared by writing 1 into the QSPI_MCR[CLR_TXF] bit.
2. Program the address related to the command in the QSPI_SFAR register.
3. Provide initial data for the program command into the circular buffer via register TX Buffer Data Register (QSPI_TBDR). At least four word of data must be written into the TX Buffer up to a maximum of 32.
4. Program the QSPI_IPCR register to trigger the command. The QSPI_IPCR[SEQID] should point to an index of the LUT which has the flash program sequence pre-programmed. The IDATSZ field should be set to denote the size of the write.

5. Depending on the amount of data required, step 3 must be repeated until all the required data have been written into the QSPI_TBDR register. The QSPI_SR[TXFULL] can be used to check if the buffer is ready to receive more data. At any time, the QSPI_TBSR[TRCTR] field can be read to check how many words have been written actually into the TX Buffer.

Upon writing the QSPI_IPCR[SEQID] field (refer to step 4) the QuadSPI module will start to execute the programmed sequence. It is the responsibility of the software to ensure that a correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX Buffer. It consists of **32** entries of 32-bits and is organized as a circular FIFO, whose read pointer is incremented by four after each fetch. When all data are transmitted, the QuadSPI module will return from 'busy' to 'idle'. However, this is not true for the external device since the internal programming is still ongoing. It is up to the user to monitor the relevant status information available from the serial flash device and to ensure that the programming is finished properly.

43.5.3.7 Flash Read

Host access to the data stored in the external serial flash device is done in two steps. First, the data must be read into the internal buffers and in the second step these internal buffers can be read by the host.

1. Reading Serial Flash Data into the QuadSPI Module Internal Buffers

A read access to the external serial flash device can be triggered in two different ways:

- **IP Command Read:** For **reading flash data into the RX Buffer** the user must provide the correct sequence ID in the QuadSPI_IPCR[SEQID] register. The sequence ID points to a sequence in the LUT. It is the responsibility of the software to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash device connected on board. The user should program the Serial Flash Address Register (QSPI_SFAR) and the IP Configuration Register (QSPI_IPCR) registers. All available read commands supported by the external serial flash are possible.

Optionally it is possible to clear the RX Buffer pointer prior to triggering the IP Command by writing a 1 into the QuadSPI_MCR[CLR_RXF] field.

From these inputs, the complete transaction is built when the QSPI_IPCR[SEQID] field is written. The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash

device into the RX Buffer. Since the read access is triggered by an IP command, the IP_ACC status bit and the BUSY bit are both set (both are located in the Status Register (QSPI_SR)). A count of the number of entries currently in the Rx Buffer can be obtained from QSPI_RBCT[RXBRD].

The communication with the external serial flash is stopped when the specified number of bytes has been read (successful completion of the transaction).

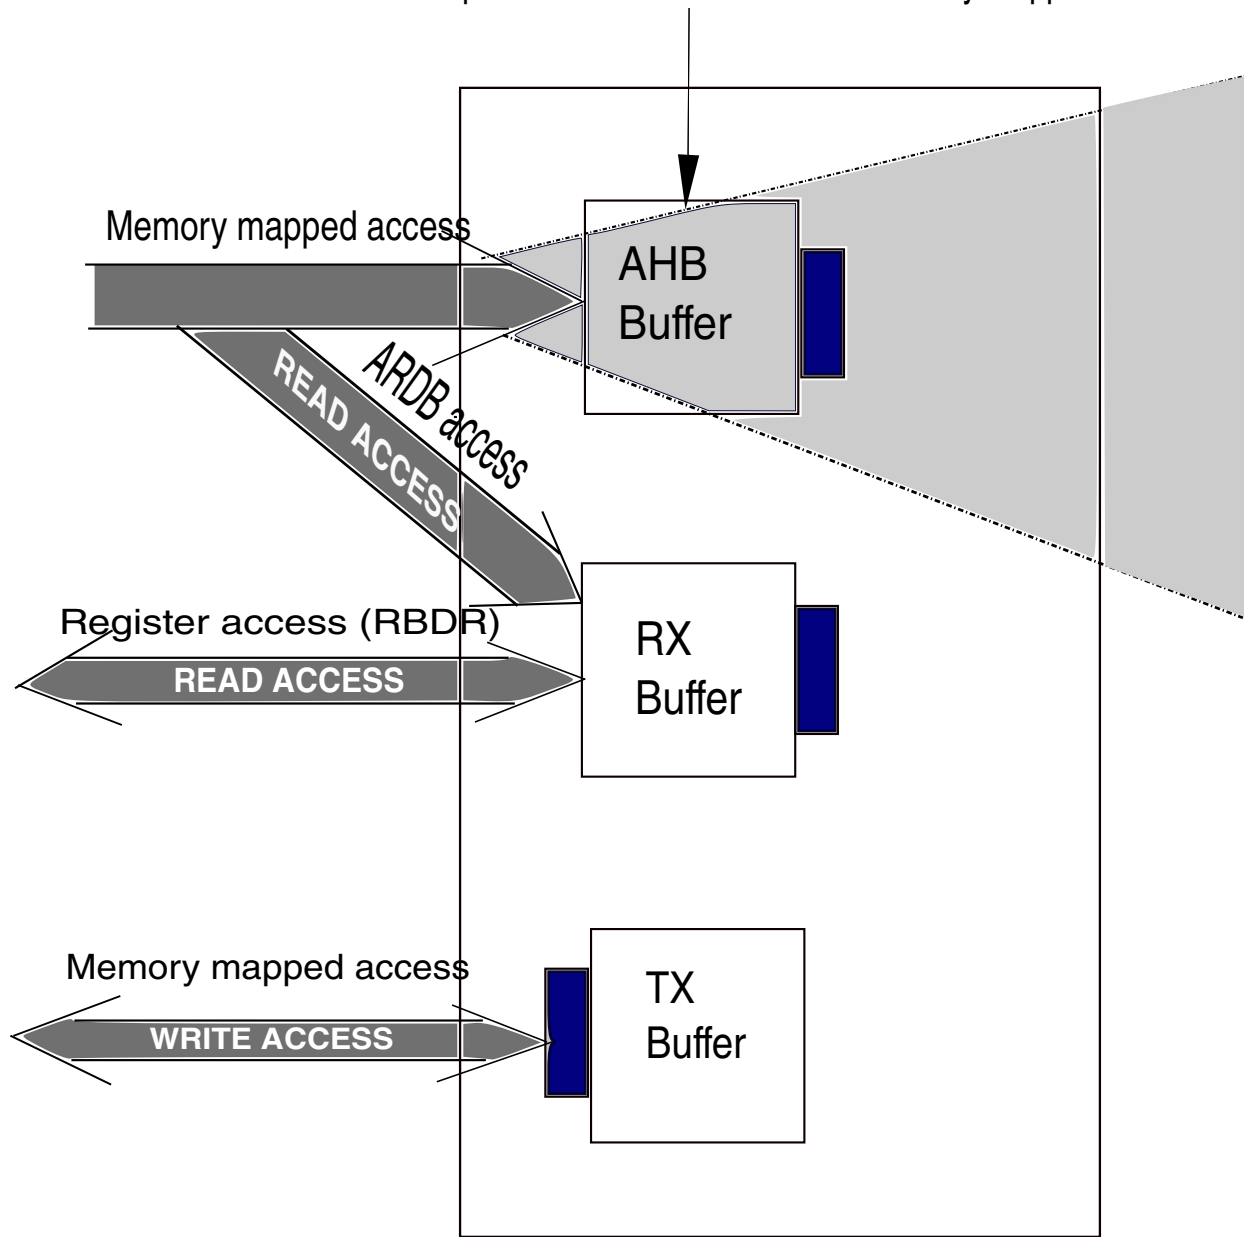

- **AHB Command Read:** For **reading flash data into the AHB Buffer** the user must set up a read access by a master to the address range in the system memory map which the external serial flash devices are mapped to. The user should also program the buffer registers corresponding to the AHB master initiating the request, this is depends on the configuration of the QSPI_RBCT[RXBRD]. The user should provide the correct sequence ID into the buffer generic configuration register (QSPI_BFGENCR). It is the responsibility of the software to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash device connected on board. Flash device selection and access mode are determined by the address accessed in the AHB address space associated to the QuadSPI module (refer to [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A](#), [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B](#) and [Parallel Flash Mode](#).)

On each AHB read access to the memory mapped area the valid data in the AHB Buffer is checked against the address requested in the actual read. When the AHB read request can't be served from the content of the AHB Buffer, the buffer is flushed and the sequence pointed to by the sequence ID is executed by the controller. The requested number of buffer entries defined in the QSPI_BUFxCR[ADATSZ] field is then fetched from the external serial flash device into the internal AHB Buffer. Since the read access is triggered via the AHB bus, the QSPI_SR[AHB_ACC] status bit is set driving in turn the QSPI_SR[BUSY] bit until the transaction is finished. The communication with the external serial flash is stopped when the specified number of entries has been filled.

2. Data Transfer from the QuadSPI Module Internal Buffers

The data read out from the external serial flash device by the QuadSPI module is stored in the internal buffers. The means of accessing the data from the buffer differs depending on which buffer the data has been loaded to. Refer to [Block Diagram](#) for details about the two available buffers, the RX Buffer and the AHB Buffer, in the QuadSPI module:

This Buffer is transparent to the user and is non-memory mapped

Note:  Byte Swapper for endianness

Figure 43-5. QuadSPI memory map

- The RX Buffer is implemented as FIFO of depth 32 entries of 4 bytes. Its content is accessible in two different address areas both referring to the identical data and the same physical memory.

In the IPS address space in the area associated to QSPI_RBDR0 to QSPI_RBDR31
 In the AHB address space in the area associated to QSPI_ARDB0 to QSPI_ARDB31. Two successive entries are accessed with one single 64 bit AHB read operation.

RX Buffer operation can be summarized as follows: The QSPI_RBCT[WMRK] field determines at which fill level the RXWE bit is asserted and how many entries are removed from the RX Buffer on each Buffer POP operation. So the QSPI_SR[RXWE] bit indicates that the configured number of data entries is available in the RX Buffer and the QSPI_RBSR[RDBFL] field indicates how many valid entries are available in total. Note that the first entry (QSPI_RBDR0 or QSPI_ARDB0) always corresponds to the first valid entry in the RX Buffer. The software needs to manage the number of valid data bytes itself.

Further details can be found in [RX Buffer Data Register \(QuadSPI_RBDR \$n\$ \)](#) and in [AHB RX Data Buffer \(QSPI_ARDB0 to QSPI_ARDB31\)](#).

- **Flag-based Data Read of the RX Buffer** is done by polling the QSPI_SR[RXWE] bit. When it is asserted the valid entries can be read either via the IPS address space (QSPI_RBDR n) or the AHB address space (QSPI_ARDB n). A Buffer POP operation must be triggered by the application by writing a 1 into the QSPI_FR[RBDF] bit - this automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. For example, if WMRK is set to 3, then the buffer will discard 16 bytes of data.
- **DMA controlled Data Read of the RX Buffer** is done by using the DMA module. The application must ensure that the DMA controller of the related device is programmed appropriately like it is described in [DMA Usage](#).

DMA controlled read out is triggered fully automatically by the assertion of the QSPI_SR[RXWE] bit. The related Buffer POP operation is also handled completely inside the QuadSPI module. Like in the case above, accessing the RX Buffer content either on QSPI_RBDR n or QSPI_ARDB n related addresses is equivalent.

- **AHB Buffer data read via memory mapped access:** This kind of access is done by reading one of the addresses assigned to the external serial flash device(s) within the range given in [Table 43-6](#) table *under the condition that the data requested are already present in the AHB Buffer or it is currently being read from the serial flash device by the instruction in progress*. If this is not the case a memory mapped AHB command read is triggered as described above. If the requested data is already available in the AHB Buffer they are provided directly to the host.

When AHB access are made to the flash memory mapped address, the data will be fetched and returned to the AHB interface. Till the data is being fetched the AHB interface would be stalled. As soon as the data from the requested address has been read by the QuadSPI module the AHB read access is served. So it is possible to run sequential reads from the AHB buffer at arbitrary speed without

the need to monitor any information about the availability of the data. Nevertheless this access scheme stalls the AHB bus for the time required to read the data from the serial flash device. A better way is (when it is known the access is sequential) to have a prefetch enabled (by programming the ADATSZ field) such that before the next sequential AHB access come, the data is already fetched into the buffer.

As long as the host restricts its accesses to the data already in the buffer and the data currently fetched from the serial flash, it is possible to run the host read from the AHB Buffer in parallel to the serial flash read into the AHB Buffer.

43.5.3.8 Byte Ordering of Serial Flash Read Data

In this paragraph the byte ordering of the serial flash data is given. The basic scheme is that the **first** byte read out of the serial flash device - which is addressed by the QSPL_SFAR[SFADR] field - corresponds to bit position QSPL_RBDR0[31:24] register for IP Command read. In contrast to that for AHB Command read the bytes are always positioned according to the byte ordering of the AHB bus.

- **Byte Ordering in Individual Flash Mode**

The following table gives the byte ordering scheme of how the byte oriented data space of the serial flash device is mapped into one single 32 bit entry of the RX Buffer or the AHB Buffer. The table is valid within the following context:

- Flash A or Flash B in Individual Flash Mode
- All AHB data read commands with access size of 32 bit

Table 43-14. Byte Ordering in Individual Flash Mode

Serial Flash Byte Numbering	3	2	1	0
Buffer Entry Bit Position [31:0] (32 Bit data width)	[31:24]	[23:16]	[15:8]	[7:0]

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

For AHB Commands, reads, starting from an address not aligned to 32 bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

• Byte Ordering in Parallel Flash Mode

In Parallel Flash Mode each byte is combined out of 2 half bytes which are read in parallel from the two serial flash devices. The following tables shows how the flash content is separated into the half bytes and how the half bytes are assembled to the content of the QSPI_RBDR0 register.

Table 43-15. Serial Flash Device Half Byte Ordering

Serial Flash Device Byte #	Flash A Bit Position		Flash B Bit Position	
	[7:4]	[3:0]	[7:4]	[3:0]
0	fah0	fal0	fbh0	fb10
1	fah1	fal1	fbh1	fb11
2	fah2	fal2	fbh2	fb12
3	fah3	fal3	fbh3	fb13
4	fah4	fal4	fbh4	fb14
5	fah5	fal5	fbh5	fb15
6	fah6	fal6	fbh6	fb16
7	fah7	fal7	fbh7	fb17
8	fah8	fal8	fbh8	fb18

The table entry naming reflects the half byte positioning in the serial flash devices:

- **<fa>h0** means **Flash A**, **<fb>h0** means **Flash B**.
- **fa<h>0** means half byte in **high position**, **fa<l>0** means half byte in **low position**.
- **fah<0>** means **physical byte address 0** in the serial flash device, **fal<1>** means **physical byte address 1** in the serial flash device.

Table 43-16. Byte Ordering in Parallel Flash Mode - RX Buffer

QSPI_SFAR[SFADR] set to 0x000_0000

Table continues on the next page...

Table 43-16. Byte Ordering in Parallel Flash Mode - RX Buffer (continued)

QSPI_RBDR0 QSPI_ARDB0	fal1	fbl1	fah1	fbh1	fa0	fb0	fah0	fbh0
QSPI_RBDR1 QSPI_ARDB1	fal3	fbl3	fah3	fbh3	fa2	fb2	fah2	fbh2
QSPI_SFAR[SFADR] set to 0x000_0001								
QSPI_RBDR0 QSPI_ARDB0	fa2	fb2	fah2	fbh2	fa1	fb1	fah1	fbh1
QSPI_RBDR1 QSPI_ARDB1	fa4	fb4	fah4	fbh4	fa3	fb3	fah3	fbh3

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4 the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

* Applicable only for single io mode.

Table 43-17. Byte Ordering in Parallel Flash Mode - AHB Buffer

AHB Address (32 Bit Access)	fal1	fbl1	fah1	fbh1	fa0	fb0	fah0	fbh0
AHB Address 0x800_0004 (32 Bit Access)	fal3	fbl3	fah3	fbh3	fa2	fb2	fah2	fbh2

Note

For AHB Command read starting from an address not aligned to 32 bit boundaries or AHB access size smaller than 32 bit the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

• Buffer Entry Ordering for 64 Bit Read Access

For read access via the AHB interface 64 bit access is possible. Each 64 bit access reads 2 32 bit entries simultaneously. The ordering of these 32 bit entries within the 64 bit word is given in the following table.

Table 43-18. 64 Bit Read Access Buffer Entry Ordering

AHB Read Data Bit Position [63:0]	[63:32]	[31:0]
Buffer Entry #	Odd (1, 3, 5, ...)	Even (0, 2, 4, ...)

43.5.3.9 Normal Mode Interrupt and DMA Requests

The QuadSPI module has different flags that can only generate interrupt requests and one flag that can generate interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are related to the [Flag Register \(QSPI_FR\)](#).

Table 43-19. Interrupt and DMA Request Conditions

Condition	Flag(QSPI_FR)	DMA
Data Learn pattern Failure	DLPFF	-
TX Buffer Fill	TBFF	-
TX Buffer Underrun	TBUF	-
Illegal Instruction Error	ILLINE	-
RX Buffer Drain	RBDF	X
RX Buffer Overflow	RBOF	-
AHB Buffer Overflow	ABOF	-
AHB Sequence Error	ABSEF	-
IP Command Usage Error	IUEF	-
IP Command Trigger during AHB Access Error	IPAEF	-
IP Command Trigger could not be executed Error	IPIEF	-
IP Access during AHB Grant Error	IPGEF	-
IP Command related Transaction Finished	TFF	-

Each condition has a flag bit in the [Flag Register \(QSPI_FR\)](#) and a Request Enable bit in the [DMA Request Select and Enable Register \(QSPI_RSER\)](#). The RX Buffer Drain Flag (RBDF) has separate enable bits for generating IRQ and DMA requests. Note that not all flags have an individual IRQ line. Check the devices Interrupt Vector Table for more details.

- **Transmit Buffer Fill Interrupt Request:**

The Transmit Buffer Fill IRQ indicates that the TX Buffer can accept new data. It is asserted if the QSPI_FR[TBFF] flag is asserted and if the corresponding enable bit (QSIP_RSER[TBFIE]) is set. Refer to [TX Buffer Operation](#), for details about the assertion of the QSPI_FR[TBFF] flag.

- **Receive Buffer Drain Interrupt or DMA Request:**

The Receive Buffer Drain IRQ derived from the QSPI_FR[RBDF] flag indicates that the RX Buffer of the QuadSPI module has data available from the serial flash device to be read by the host. It remains set as long as the QSPI_RBSR[RXWE] bit is set. The QSPI_RSER[RBDIE] bit enables the related IRQ.

Aside from the IRQ it is possible to handle RX Buffer drain by DMA. If the QSPI_RSER[RBDDE] bit is set, a DMA request will be triggered when the RX Buffer contains more than QSPI_RBCT[WMRK] valid entries. The application must set the environment appropriately (for example, the DMA controller) for the DMA transfers.

- **Buffer Overflow/Underrun Interrupt Request:**

The Buffer Overflow/Underrun IRQ is a combination of the following flags (all located in the QSPI_FR register with the related enable bits in the QSPI_RSER register):

- TBUF - TX Buffer Underrun, enabled by TBUIE
- RBOF - RX Buffer Overflow, enabled by RBOIE
- ABOF - AHB Buffer Overflow, enabled by ABOIE

The Transmit Buffer Underrun indicates that an underrun condition in the TX Buffer has occurred. It is generated when a write instruction is triggered whilst the Tx Buffer is empty and the QSPI_RSER[TFUFIE] bit is set.

The Receive Buffer Overflow indicates that an overflow condition in the RX Buffer has occurred. It is generated when the RX Buffer is full, an additional read transfer attempts to write into the RX Buffer and the QSPI_RSER[RBOIE] bit is set.

The AHB Buffer Overflow indicates that an overflow condition in the AHB Buffer has occurred. It is generated when the AHB Buffer is full, an additional read transfer attempts to write into the AHB Buffer and the QSPI_RSER[ABOIE] bit is set.

The data from the transfers that generated the individual overflow conditions is ignored.

- Serial Flash Command Error Interrupt Request

If the IPAEF, IPIEF, IPGEF or IUEF flags in the QSPI_FR are set, and the related interrupt enable bits in the QSPI_RSER are also set, then an interrupt is requested.

- Transaction Finished Interrupt Request

The IP Command Transaction Finished IRQ indicates the completion of the current IP Command. It is triggered by the QSPI_FR[TFF] flag and is masked by the QSPI_RSER[TFIE] bit.

43.5.3.10 TX Buffer Operation

The TX Buffer provides the data used for page programming. For proper operation it is required to provide at least four entry in the TX Buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX Buffer fast enough as long as the command is executed without a TX Buffer overflow or underrun.

The QuadSPI module sets the QSPI_FR[TBFF] flag so long as the TX Buffer is not full and can accept more data.

When the QuadSPI module tries to pull data out of an empty TX Buffer the TX Buffer underrun is signaled by the QSPI_FR[TBUF] flag. The TX buffer underrun flag is also asserted when TX buffer contains less than 128 bits of data and QuadSPI module tries to pull out data from it. The current IP Command leading to the underrun condition is continued until the specified number of bytes has been sent to the serial flash device, in the underrun condition when QuadSPI module tries to pull out data of empty TX buffer, the data transferred is all F's i.e. once the underrun flag is set under this condition, it will return F's until the required number of bytes are not sent. This has been done to ensure that the software need not to erase whole sector after underrun, just reprogramming from failure point will serve the purpose. When this Sequence Command is finished, the QSPI_FR[TBFF] flag is asserted indicating that the Tx Buffer is ready to be written again.

The TX Buffer overflow isn't signaled explicitly, but the TX Buffer fill level can be monitored by the QSPI_TBSR[TRBFL] field.

Refer to [TX Buffer Status Register \(QuadSPI_TBSR\)](#) and [Flag Register \(QuadSPI_FR\)](#) for details about the TX Buffer related registers.

43.5.3.11 Address scheme

Earlier serial flash memories supported only 24-bit address space hence restricting the maximum memory size of the serial flash as 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to legacy 24-bit address mode.

- **Extended Address Mode**

In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The flash memory needs to be configured for 32-bit address mode. Also, while programming the LUT sequence in QuadSPI for 32-bit mode, the ADDR and ADDR_DDR command should be programmed with 8'd32 as the operand value. By default, the QuadSPI is in 24-bit legacy address mode. Each of the memory vendors have a different way of enabling this mode (Refer to the memory specification from memory vendors). For example, the command B7h sent to Macronix flash will enable it for 32-bit address mode.

- **Extended Address register**

In this mode, the upper 8-bit of the 32-bit address is provided by the Extended address register in the memory itself. The memory provides a specific register which is updated according to the address to be accessed. This effectively converts the legacy 24-bit address command into 32-bit address commands. The memories greater in size than 16 MB, consists of banks of 16 MB. The 8-bit written in the extended address register effectively enables a bank. For example in Spansion memory, when the extended address register is updated with a value of 0x01 with the help of the command 17h, it will open Bank1 of the memory. The consequent 24-bit address commands will lead to Bank1. The extended address register needs to be update with the respective value for access to other banks. This effectively converts the legacy 24-bit address command into 32-bit address commands.

43.6 Initialization/Application Information

This section provides the initialization and application information of the QuadSPI module.

43.6.1 Power Up and Reset

Note that the serial flash devices connected to the QuadSPI module may require special voltage characteristics of their inputs during power up or reset. It is the responsibility of the application to ensure this.

43.6.2 Available Status/Flag Information

This paragraph gives an overview of the different status and flag information available and their interdependencies for different use cases. Related registers are QSPI_SR and QSPI_FR. Refer to the related descriptions how to set up the QuadSPI module appropriately.

43.6.2.1 IP Commands

Refer to [IP Configuration Register \(QuadSPI_IPCR\)](#) for additional details not explicitly covered in this paragraph.

- **IP Commands - Normal Operation**

Writing the QSPI_IPCR[SEQID] field triggers the execution of a new IP Command. Given that this is a legal command the QSPI_SR[IPACC] and the QSPI_SR[BUSY] bits are asserted simultaneously, immediately after the execution is started.

When the instruction on the serial flash device has been finished these bits are de-asserted and the QSPI_FR[TFF] flag is set.

- **IP Commands - Error Situations**

Refer to [Table 43-20](#) below.

43.6.2.2 AHB Commands

Refer to Section 1, Reading Serial Flash Data into the QuadSPI Module, in [Flash Read](#) for additional details not explicitly covered in this paragraph.

- **AHB Commands - Normal Operation**

Memory mapped read access to a serial flash address not contained in the AHB Buffer, triggers the execution of an AHB Command. Given that this is a legal command the QSPI_SR[AHBACC] and the QSPI_SR[BUSY] bits are asserted simultaneously immediately after the execution is started. When the instruction on the serial flash device has been finished these bits are de-asserted.

- **IP Commands - Error Situations**

Refer to [Table 43-20](#) below.

43.6.2.3 Overview of Error Flags

The following table gives an overview of the different error flags in the QSPI_FR register and additional error-related details.

Table 43-20. Overview of QSPI_FR Error Flags

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
AHB Error Flag	ABSEF	Flash transaction is aborted	AHB sequence contains <ul style="list-style-type: none"> • WRITE instruction • WRITE_DDR instruction
AHB Error Flag	ABOF	Flash transaction continues until it finishes	Set when the module tried to push data into the AHB buffer that exceeded the size of the AHB buffer. Only occurs due to wrong programming of the QSPI_BUFxCR[ADATSZ].
Miscellaneous Error Flag	DLFFF ¹	Flash transaction continues until it finishes	Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern.
Miscellaneous Error Flag	ILLINE	Flash transaction aborted	Illegal instruction Error Flag – Set when an illegal instruction is encountered by the controller in any of the sequences.
Command Arbitration Error	IPIEF	TFF not asserted in conjunction with that command	IP Command Error - caused when IP access is currently in progress (IP_ACC set) and <ul style="list-style-type: none"> • write attempt to QSPI_IPCR register. • write attempt to QSPI_SFAR register. • write attempt to QSPI_RBCT register.
Command Arbitration Error	IPAEF		<ul style="list-style-type: none"> • AHB Command already running, another IP Command could not be executed. • AHB Command already running, write attempt to QSPI_IPCR[SEQID] field.
Command Arbitration Error	IPGEF		<ul style="list-style-type: none"> • Exclusive access to the serial flash granted for AHB Commands, write attempt to QSPI_IPCR[SEQID] field.
IP Command Error	IUEF	—	<ul style="list-style-type: none"> • IP Command Usage Error

Table continues on the next page...

**Table 43-20. Overview of QSPI_FR Error Flags
(continued)**

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
Buffer Related Error	RBOF	TFF is asserted on completion	<ul style="list-style-type: none"> RX Buffer Overrun
Buffer Related Error	TBUF		<ul style="list-style-type: none"> TX Buffer Underrun

1. Data learning is not implemented on this chip.

Note that only the buffer related errors are related to a transaction on the external serial flash. All the other errors do not trigger an actual transaction.

43.6.2.4 IP Bus and AHB Access Command Collisions

There are two flags related to this topic, the QSPI_FR[IPAEF] and QSPI_FR[PIEF]. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for a description of the flags and [Command Arbitration](#), for details about possible command collisions.

43.6.3 Exclusive Access to Serial Flash for AHB Commands

It is possible that several masters need to access the serial flash device connected to the QuadSPI module separately, one master by triggering IP Commands and reading the RX Buffer (via RBDR n register) and the other masters by triggering AHB Commands (via ARDB n Registers). These two set of buffer (RBDR and ARDB Buffer) points to the same physical buffer. Refer to [Figure 43-5](#) To avoid command collisions resulting in excessive latencies the QuadSPI module implements a request-handshake mechanism between the master triggering AHB Commands and the QuadSPI module allowing this specific master to request exclusive access to the serial flash device for AHB Commands. If this exclusive access is granted the execution of IP Commands is blocked. This resolves command collisions and excessive times where the AHB interface may be blocked.

If this capability is used in the device there is additional status and flag information available related to this mechanism. The QSPI_SR[AHBGNT] bit reflects the module-internal state that the exclusive access mentioned above is granted, any attempt to trigger an IP Command is rejected and results in the assertion of the QSPI_FR[IPGEF] flag. Refer to the descriptions of the related bit and flag for details.

It is within the responsibility of the application to set up the master using this mechanism appropriately, if used incorrectly no IP Commands at all can be triggered.

Two different cases can be distinguished:

43.6.3.1 RX Buffer Read via QSPI_ARDB Registers

In this case all masters share the AHB bus for RX Buffer as well as for AHB Buffer read. In this case the access to the AHB interface by the master triggering AHB Commands must be deferred until any pending IP Command has been finished **and** the RX Buffer readout has been finished as well. The QSPI ARDB Buffers access the Rx buffer i.e the data from the Rx Buffer is returned and no data from AHB Buffer is touched. This is the conservative use case, corresponding to the reset value 0 of the QSPI_RBCT[RXBRD] bit.

In this case the QSPI_SR[AHBGNT] bit is asserted not earlier than any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0 and Rx Buffer readout is via AHB(QSPI_RBCT[RXBRD]) equal to 1).

43.6.3.2 RX Buffer Read via QSPI_RBDR Registers

This is the preferred use case as an access to the AHB buffer (memory mapped flash) does not interfere with any IPS access to read the RBDR buffer. It is not possible that a pending AHB bus access triggered by an AHB Command stalls the AHB bus and blocks the RX Buffer readout since the RX Buffer is read via the IP bus based registers QSPI_RBDR0 to QSPI_RBDR31.

For this case it is recommended to program the QSPI_RBCT[RXBRD] bit to 1. The QSPI_SR[AHBGNT] bit is asserted immediately after any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0), allowing the master triggering AHB Commands to trigger AHB Commands as soon as possible without the need to wait for the RX Buffer readout to be finished.

43.6.4 Command Arbitration

In case of overlapping commands, the arbitration scheme is described in the following paragraphs under the assumption that the priority mechanism described in [Exclusive Access to Serial Flash for AHB Commands](#) is **not** used:

- During the execution of an IP Command, the running IP Command can't be terminated by issuing another IP Command or AHB Command. The QSPI_FR[IPIEF] flag is asserted when the host tries to write into the QSPI_IPCR register. When the host triggers an AHB Command (refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for details), this command is stalled until the currently running IP Command is finished.
- During the execution of an AHB Command, the running AHB Command can't be terminated by issuing an IP Command. The command is ignored and the QSPI_FR[IPAEF] flag is asserted. Refer to [Flag Register \(QuadSPI_FR\)](#) for the description of these flags.

When another AHB Command is triggered the address of the memory mapped access is considered. If the requested address is currently read from the serial flash device, the running command is continued. If this is not the case the currently running command is terminated and another AHB Command related to the requested address is executed. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for further details.

In case of coinciding commands the IP Command is triggered and the AHB Command is stalled until the IP Command has been finished (QSPI_SR[IP_ACC] has been deasserted).

The IP Commands ignored in case of command collision will not result in the assertion of the QSPI_FR[TFF] flag.

43.6.5 Flash Device Selection

Regardless of the SFM Command (IP or AHB) the access mode is selected by specifying the 32 bit address value for the following SFM Command.

For IP Commands the access mode is selected with the address programmed into the QSPI_SFAR register. Refer to [Serial Flash Address Register \(QuadSPI_SFAR\)](#) for details.

For AHB Commands the access mode is determined by the memory mapped address which is accessed Refer to [AMBA Bus Register Memory Map](#) for details.

43.6.6 DMA Usage

For the complete description of the DMA module refer to the related DMA Controller chapter. In this paragraph only the details specific to the DMA usage related to the QuadSPI module are given.

43.6.6.1 DMA Usage in Normal Mode

43.6.6.1.1 Bandwidth considerations

Careful consideration of the throughput rate of the entire chain (serial flash -> AHB bus / IP Bus -> DMA controller) involved in the read data process is essential for proper operation. Such analysis must take into account not only the data rate provided by the serial flash but also the data rate of the AHB bus and the performance of the DMA controller in reading data from the RX buffer.

Two figures must match for proper operation, that means that the data rate provided by the serial flash device must not exceed the average RX Buffer readout data rate. Otherwise, the longer this state persists, a RX Buffer overflow will result.

AHB Bus Side (data read):

The total number of bus cycles for each DMA Minor Loop completion is added from the following components:

- Overhead for each minor loop, given by DMA controller: Assume 10 cycles
- Overhead due to clock domain crossing: Assume 2 cycles
- Number of bus clock cycles required for 8 bytes (64 bit read size): Assume 2 cycles (read/write sequence of DMA controller)

Note that the size of the minor loop is determined by the size of the QSPI_RBCT[WMRK] field, therefore the overhead given above distributes among $(\text{QSPI_RBCT}[\text{WMRK}] + 1) / 2$ read accesses of 64 bit each.

The following table gives some examples for typical use cases:

Table 43-21. Access Duration Examples - Bus Clock Side

QSPI_RBCT[WMRK]	Number of Bytes per DMA Loop ¹	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 120Mhz Bus clock Frequency
0	4	12+2 = 14	~117ns

Table continues on the next page...

Table 43-21. Access Duration Examples - Bus Clock Side (continued)

QSPI_RBCT[WMRK]	Number of Bytes per DMA Loop ¹	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 120Mhz Bus clock Frequency
1	8	12+2 = 14	~117ns
3	16	12+4 = 16	~133ns
7	32	12+8 = 20	~167ns
11	48	12+12 = 24	~200ns

1. DMA Loop means one Minor Loop Completion which is equivalent to one.

NOTE

The table figure represents ideal scenario, actual performance will depend on how the system is integrated.

Serial Flash Device Side (data read):

The number of serial flash cycles can be determined in the following way:

- Number of serial flash clock cycles required to read 4 bytes, corresponding to one RX Buffer entry (setup of command and address not considered): 2 cycles for Quad DDR mode instructions in Parallel Flash Mode, 4 cycles for Quad (SDR) mode instruction in parallel flash mode or Dual IO DDR mode instruction in parallel flash mode, 8 cycles for Quad Mode (SDR) instructions in Individual Flash Mode etc.
- Overhead due to clock domain crossing : 1 cycle.

The following table lists the number of clock cycles required to read the data from the serial flash corresponding to the different settings of the QSPI_RBCT[WMRK] field:

Table 43-22. Access Duration Examples - Serial Flash side

QSPI_RBCT[WMRK] setting	Num Bytes per DMA Loop ¹	Num SCKFx for 60MHz SCKFx			Time duration of Flash data readout for 60MHz SCKFx (~16.6ns period)		
		IFM ² Quad	IFM Quad DDR	PFM ³ Quad DDR	IFM Quad	IFM Quad DDR	PFM Quad DDR
0	4	9	5	3	~150ns	~83ns	~50ns
1	8	17	9	5	~282ns	~150ns	~83ns
3	16	33	17	9	~548ns	~282ns	~150ns
7	32	65	33	17	~1079ns	~548ns	~282ns
11	48	97	49	25	~1610ns	~813ns	~415ns

1. DMA Loop means one Minor loop completion which is equivalent to one Major Loop iteration.
2. Individual flash mode.
3. Parallel flash mode.

From the examples given in the two tables above, it can be seen that depending on the relationship between the Bus clock and Serial flash clock frequencies, there are settings possible where the serial flash provides the read data faster than the AHB bus can read out the RX buffer. In the above tables, it is the case of PFM Quad DDR mode with Watermark up to 3 and other cases. In these cases, the RX buffer data keeps accumulating over time and will eventually overflow. To avoid RX Buffer overflow, the data transaction size should be small enough.

A complementary example would be when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be smaller than the time taken by the controller to push in the remaining entries in the buffer.

NOTE

The tables mentioned above are only examples which must be correlated with the DMA in the system.

43.6.7 Parallel mode

QuadSPI can access two flashes in parallel. This increases the throughput of the QuadSPI by two times. Only read operations are allowed in parallel mode. In case a write transaction is initiated in parallel mode, QSPI_FR[IUEF] is set. When dual die flashes are accessed in parallel mode, it is mandatory for flash A1 to be of the same size as B1 and A2 to be of the same size as B2. The following figure shows how QuadSPI maps the incoming addresses to the different flashes connected on board.

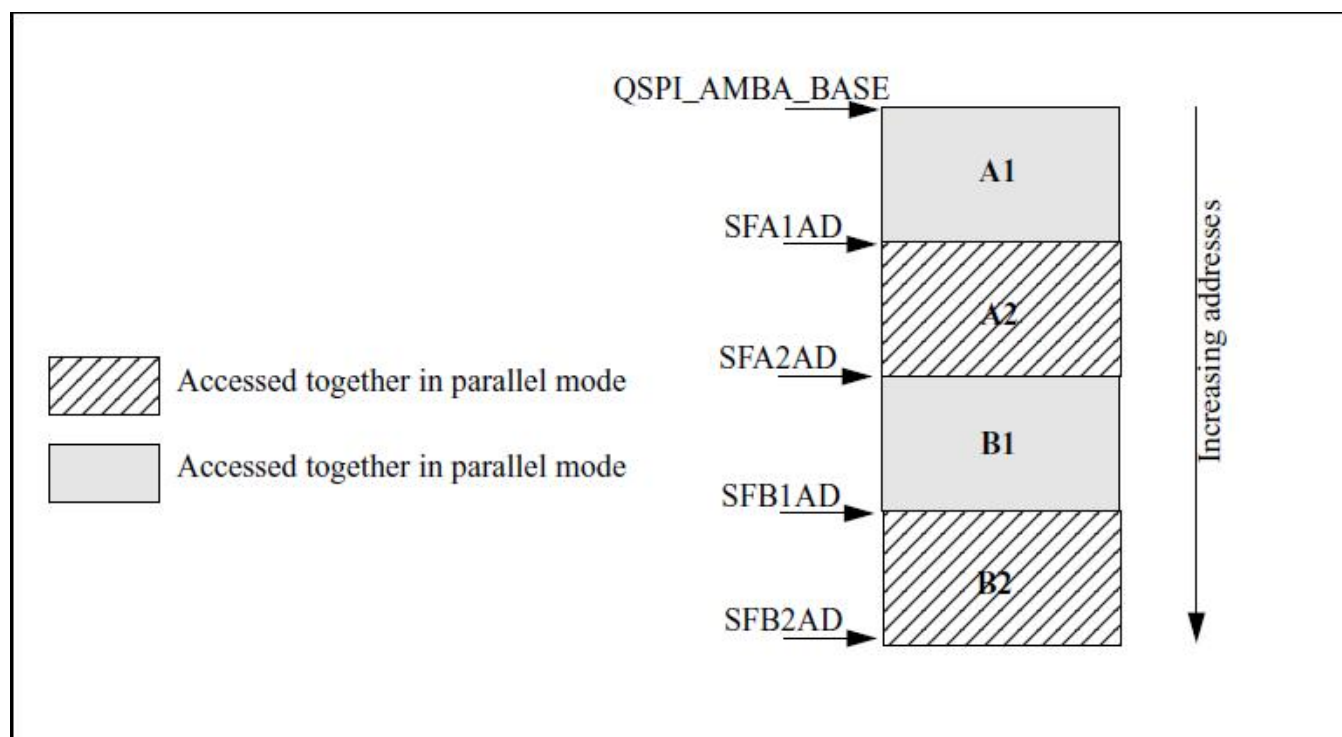

Figure 43-6. Flash addressing

An example programming for parallel mode access is given below (flash sizes are assumed to be 256MB):

- QSPI_AMBA_BASE - 0x10000000
- QSPI_SFA1AD[TPADA1] - 0x20000000
- QSPI_SFA2AD[TPADA2] - 0x30000000
- QSPI_SFB1AD[TPADB1] - 0x40000000
- QSPI_SFB2AD[TPADB2] - 0x50000000

In order to access the first location of A1/B1 pair, the incoming address should be 0x10000000. QSPI_AMBA_BASE is subtracted from this address and the result is divided by two. Therefore, address provided to flash A1 and B1

$$\text{Flash Address} = (\text{Memory mapped address} - \text{QSPI_AMBA_BASE})/2$$

For Memory Mapped address:

- 0x10000000, flash address: 0x0 (Or, the first address of flash A1 and B1)
- 0x10000004, flash address: 0x2
- 0x10000008, flash address: 0x4 etc.

Similarly, in order to access the first location of A2/B2 pair, the incoming address should be 0x30000000.

$$\text{Flash Address} = (\text{Memory mapped address} - \text{SFA2AD})/2$$

For Memory Mapped address:

- 0x30000000, flash address: 0x0 (Or, the first address of flash A2 and B2)
- 0x30000004, flash address: 0x2
- 0x30000008, flash address: 0x4 etc.

Figure 43-7. Memory map - Serial and Parallel

43.7 Byte Ordering - Endianness

QuadSPI provides support for swapping the flash read/write data based on the configuration of the QSPI_MCR[END_CFG]. By default the data is always returned in 64 bit LE format on the AHB bus and 32 bit LE format on the IPS interface when read via the RX buffer and written in 32 bit LE format when written via the TX buffer.

The table(QSPI_MCR[END_CFG]) below shows the complete bit ordering. BE signifies Big Endian which means the high order bits of the associated data vectors are associated with low order address positions. LE signifies Little Endian which means the lower order bits of the associated data vectors are associated with low order address positions. Refer to figure [Figure 43-5](#)

Table 43-23. QSPI_MCR[END_CFG]

00	64 bit BE
01	32 bit LE
10	32 bit BE
11	64 bit LE

The tables below (Byte ordering configuration in AHB) and (Byte ordering configuration in IPS) show how this configuration is implemented in QSPI AHB and IPS interfaces respectively. B in the table signifies Byte and the index 1-8 refers to the byte position i.e. 1 refer to bits[7:0], 8 refer to bits[63:56] and so on.

Table 43-24. Byte ordering configuration in AHB

64 bit BE	B1	B2	B3	B4	B5	B6	B7	B8
64 bit LE	B8	B7	B6	B5	B4	B3	B2	B1
32 bit BE	B5	B6	B7	B8	B1	B2	B3	B4
32 bit LE	B4	B3	B2	B1	B8	B7	B6	B5

Table 43-25. Byte ordering configuration in IPS

32BE	B1	B2	B3	B4
32LE	B4	B3	B2	B1

The examples below show the byte ordering in 64 bit BE configuration for AHB Buffer and 32 bit BE for TX/RX Buffer:

43.7.1 Programming Flash Data

CPU write instructions to the QSPI_TBDR register like

- Write QSPI_TBDR -> 0x01_02_03_04
- Write QSPI_TBDR -> 0x05_06_07_08

result in the following content of the TX Buffer:

Table 43-26. Example of QuadSPI TX Buffer

TX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

Programming the TX Buffer into the external serial flash device results in the following byte order to be sent to the serial flash:

- 01...02...03...04...05...06...07...08

43.7.2 Reading Flash Data into the RX Buffer

Reading the content from the same address provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

This results in the RX Buffer filled with:

Table 43-27. Resulting RX Buffer Content

RX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

43.7.2.1 Readout of the RX Buffer via QSPI_RBDRn

The RX Buffer content appears at CPU read access via the Peripheral bus interface in the following order:

- Read QSPI_RBDR0 <- 0x01_02_03_04
- Read QSPI_RBDR1 <- 0x05_06_07_08

43.7.2.2 Readout of the RX Buffer via ARDBn

The RX Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04
- (2a): 32 Bit Access: Read QSPI_ARDB1 <- 0x05_06_07_08
- (1b/2b): 64 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04_05_06_07_08

43.7.3 Reading Flash Data into the AHB Buffer

Reading the content from the same address as it was written to provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

This results in the AHB Buffer filled with:

Table 43-28. Resulting AHB Buffer Content

AHB Buffer Entry	Content
0	64'h01_02_03_04_05_06_07_08

43.7.3.1 Readout of the AHB Buffer via Memory Mapped Read

The AHB Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Read Access: <- 0x01_02_03_04
- (2a): 32 Bit Read Access: <- 0x05_06_07_08
- (1/2): 64 Bit Read Access: <- 0x01_02_03_04_05_06_07_08

43.8 Serial Flash Devices

Several different vendors make flash devices with a QuadSPI interface. At present there is no set standard for the QuadSPI instruction set. Most common commands currently have the same instruction code for all vendors, however some commands are unique to specific vendors. Some example sequences are provided below.

43.8.1 Example Sequences

This section provides the example sequences of the QuadSPI module.

Table 43-29. Exit 4 x I/O Read Enhance Performance Mode (XIP) (Macronix) and Read Status

INSTR	PAD	OPERAND	COMMENT
CMD	0x0	0xEB	4xIO Read Command
ADDR	0x2	0x18	24 Bit address to be send on 4 pads
MODE	0x2	0x00	2 mode cycles (exit XIP)
DUMMY	0x0	0x04	4 dummy cycles
READ	0x2	0x08	Read 64 bits
CMD	0x0	0x05	Read Status register
READ	0x0	0x01	Status register data
STOP	0x0	0x00	STOP, Instruction over

43.8.1.1 Fast Read Sequence (Macronix/Numonyx/Spansion/Winbond)

The following table shows the fast read sequence for Macronix/Numonyx/Spansion/Winbond flashes.

Table 43-30. Fast Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x0B	Fast Read command = 0x0B
ADDR	0x0	0x18	24 Addr bits to be sent on one pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x0	0x04	Read 32 Bits on one pad
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

43.8.1.2 Fast Dual I/O DT Read Sequence (Macronix)

The following table shows the Fast Dual I/O DT read sequence for Macronix flashes.

Table 43-31. Fast Dual I/O DT Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xBD	Fast Dual I/O DT read command = 0xBD

Table continues on the next page...

Table 43-31. Fast Dual I/O DT Read sequence (continued)

Instruction	Pad	Operand	Comment
ADDR_DDR	0x1	0x18	24 Addr bits to be sent on 2 pads in DDR mode
MODE4_DDR	0x1	0x00	P2=P0 or P3=P1 is necessary. Refer to Macronix datasheet for details. One clock cycle for mode.
DUMMY	0x0	0x06	6 Dummy cycles
READ_DDR	0x1	0x04	Read 32 Bits on 2 pads in DDR mode
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

43.8.1.3 Fast Read Quad Output (Winbond)

The following table shows the Fast read quad output sequence for Winbond memories

Table 43-32. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x6B	Fast read quad output command = 0x6B
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

43.8.1.4 4 x I/O Read Enhance Performance Mode (XIP) (Macronix)

The following table shows the 4 x I/O Read Enhance Performance Mode for Macronix flashes. The enhanced performance mode is also known as XIP mode.

Table 43-33. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xEB	4xI/O Read command = 0xEB
ADDR	0x2	0x18	24 Addr bits to be sent on 4 pads
MODE	0x2	0xA5	2 mode cycles
DUMMY	0x0	0x04	4 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x01	Jump to instruction 1 (ADDR)

When in XIP mode the software should ensure that all the flashes connected to the controller are in XIP mode. As a part of initializing the controller, all the flashes may be enabled with XIP by carrying out dummy reads.

43.8.1.5 Dual Command Page Program (Numonyx)

The following table shows the Dual command page program sequence for Numonyx flashes.

Table 43-34. Dual Command Page Program sequence

Instruction	Pad	Operand	Comment
CMD	0x1	0x02	Dual command page program = 0x02 on 2 pads
ADDR	0x1	0x18	24 Addr bits to be sent on 2 pads
WRITE	0x1	0x20	Write 32 Bytes on 2 pads
STOP	0x0	0x00	STOP, Instruction over

43.8.1.6 Sector Erase (Macronix/Spansion/Numonyx)

The following table shows the Sector erase sequence for Macronix/Spansion/Numonyx flashes

Table 43-35. Sector Erase sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xD8	Sector erase command = 0xD8
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
STOP	0x0	0x00	STOP, Instruction over

43.8.1.7 Read Status Register (Macronix/Spansion/Numonyx/Winbond)

The following table shows the Read status register sequence for Macronix/Spansion/Numonyx/Winbond flashes.

Table 43-36. Read Status Register Sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x05	Read status register command = 0x05
READ	0x0	0x01	Read status register data
STOP	0x0	0x00	STOP, Instruction over

43.8.2 Dual Die Flashes

Certain serial flash vendors provide dual-die packages which are essentially two devices (dies) stacked within the same package to increase the memory capacity of a single package. These two devices within a package share the same data and clock pins, but have individual Chip Selects. QuadSPI controller provides support for two dual-die packages to be connected simultaneously. The figure below shows the two dual-die packages and the naming conventions used in this document. For simplicity, the data pins are shown to be unidirectional.

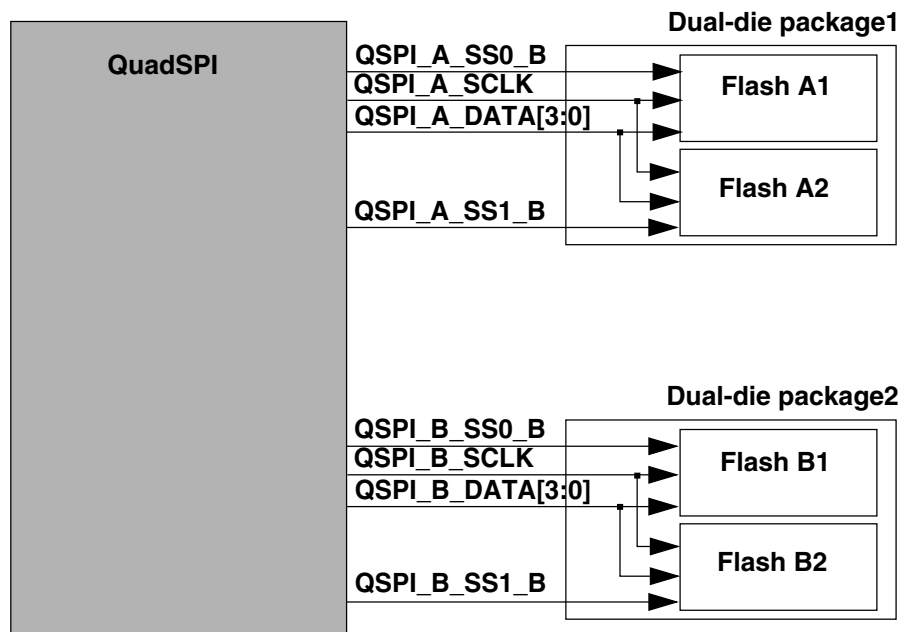

Figure 43-8. Dual-die support

Since the two devices within one package share the same i/o pads, they cannot function in parallel mode. Software should ensure that when QuadSPI is configured in parallel mode the two selected flash devices are from different dual-die packages.

43.8.3 Boot initialization sequence

The following are the recommended sequence of steps for booting from QuadSPI:

- System out of reset and flash available (300us)

- Clocks still at very low frequency. Clock tree configured, I/O pins configured. First request sent to QuadSPI for address 0x0 of flash.
- The reset command sequence in QuadSPI has 0x03 (basic read command) which is applicable to all flashes at < 50MHz serial flash clock
- The first few bytes of data is read from the flash which contains the following information:
 - The total sizes of all the flashes connected on board
 - Whether DDR mode supported
 - Frequency of DDR operation
 - Continuous mode entry sequence
 - 24bit or 32bit addressing (assuming 24bit for first accesses)
- All the serial flashes are configured
 - Quad Mode enabled
 - Dummy reads to enter into XIP
- QuadSPI is configured
 - Parallel enable set
 - LUT configured for highest performance reads
 - DDR mode enabled (if applicable)
 - Buffers configured
- Serial flash clock frequency increased.
- Boot reads happen in parallel, DDR enabled, quad output mode @66MHz.

43.9 Sampling of Serial Flash Input Data

43.9.1 Internal Sampling of Serial Flash Input Data

Depending from the actual implementation there is a delay between the internal clocking in the QuadSPI module and the external serial flash device. Refer to the following figure for an overview of this scheme.

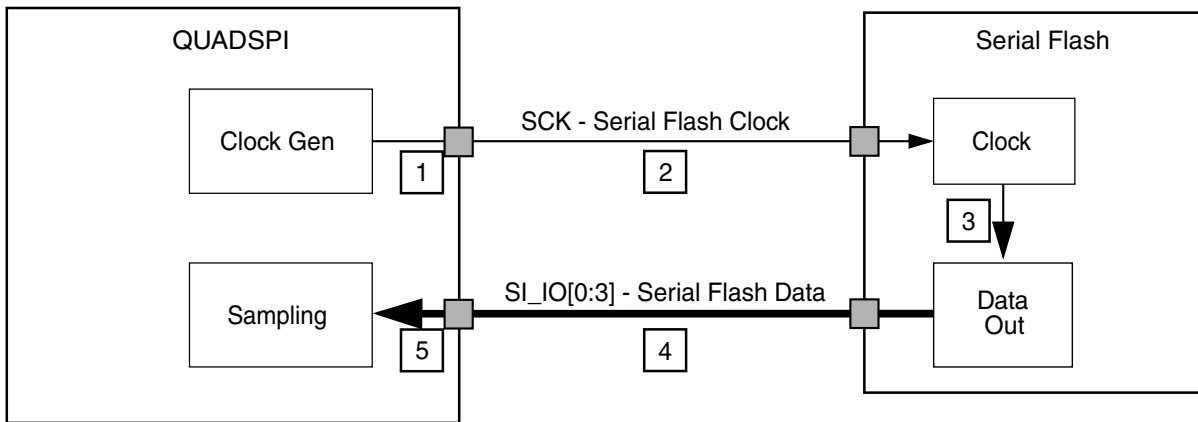

Figure 43-9. Serial Flash Sampling Clock Overview

Note

The arrival of the serial flash data in the sampling stage of the QuadSPI module are given in the following figure. Note that the amount of the total delay $t_{Del,total}$ is very specific to the characteristics of the actual implementation.

Note also that the serial flash device clock SCK is inverted with respect to the QuadSPI internal reference clock.

Figure 43-10. Serial Flash Sampling Clock Timing

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash. After a time of $t_{Del,total}$ the data arrive at the internal sampling stage of the QuadSPI module.

According to the Serial Flash Sampling Clock Overview figure, the following parts of the delay chain contribute to $t_{Del,total}$:

1. Output delay of the serial flash clock output of the device containing the QuadSPI module
2. Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash device
3. Clock to data out delay of the external serial flash device, including input and output delays
4. Wire delay of application/PCB from the external serial flash device to the device containing the QuadSPI module
5. Input delay belonging to the data in input

The possible points in time for the sampling of the incoming data are denoted as N/1, I/1, N/2 and I/2 above. The sampling point relevant for the internal sampling is configured in the QSPI_SMPR register, refer to [Sampling Register \(QuadSPI_SMPR\)](#) for details. Note that the falling edges of the reference clock are not actually used, instead the inverted clock is used for sampling at these positions. The following table gives an overview of the available configurations for the commands running at regular (full) speed:

Table 43-37. Sampling Configuration

Sampling Point	Description	Delay [FSDLY] [HSDLY]	Phase [FSPHS] [HSPHS]	QSPI_SMPR for Full Speed Setting ¹
N/1	sampling with non-inverted clock, 1 sample delay	0	0	0x0000000x
I/1	sampling with inverted clock, 1 sample delay	0	1	0x0000002x
N/2	sampling with non-inverted clock, 2 samples delay	1	0	0x0000004x
I/2	sampling with inverted clock, 2 samples delay	1	1	0x0000006x

1. 'x' is not considered here

Depending from the actual delay and the serial flash clock frequency the appropriate sampling point can be chosen. The following remarks should be considered when selecting the appropriate setting:

- Theoretically there should be 2 settings possible to capture the correct data since the serial flash output is valid for 1 clock cycle, disregarding rise and fall times and timing uncertainties.
- Depending from the timing uncertainties it may turn out in actual applications that only one possible sample positions remains. This is subject to careful consideration depending from the actual implementation.

- The delay $t_{Del,total}$ is an absolute size to shift the point in time when the serial flash data get valid at the QuadSPI input.
- For decreasing frequency of the serial flash clock the distance between the edges increases. So for large differences in the frequency the required setting may change.
- For commands running at half of the regular serial flash clock (QSPI_SMPR[HSENA] bit set) the sampling point must be figured separately to allow for the compensation of the absolute shift in time with respect to the sample-relative setting in the QSPI_SMPR register.

43.9.2 DDR Mode

The increasing requirement of improved throughput has introduced the double data rate (DDR) mode. In DDR mode, the data is transferred on both the rising and falling edges of the serial flash clock. The DDR serial flashes sample as well as drive the data on both rising and falling edges of serial flash clock.

43.10 Serial Flash Data Input Timing

There are sampling modes for input flash data:

- Internal sampling - Input serial flash data is captured by internal serial clock. In SDR mode, serial data is sampled by serial clock 1x (ser_clk_1x) rise edge. In DDR mode, serial data is sampled by serial clock 4x (ser_clk_4x) rise edge.
- Loopback DQS sampling - Soc will output serial data strobe with internal serial clock. This serial data strobe would be loopback from pad and used to sample input serial data. In SDR mode, serial data is sampled by loopback DQS rise edge. In DDR mode, serial data is sampled by loopback DQS both edge

NOTE

DQS pad need to be set to force input for loopback.

- Flash DQS sampling - Some serial Flash device provide the data strobe output together with serial data. This strobe signal is used to sample input serial data directly. In SDR mode, serial data is sampled by Flash DQS rise edge. In DDR mode, serial data is sampled by Flash DQS both edge

Following table shows selection for sampling mode:

Sampling mode	DQS_EN	DQS_LOOPBACK_EN
Internal sampling	0	doesn't matter

Table continues on the next page...

Serial Flash Data Input Timing

Sampling mode	DQS_EN	DQS_LOOPBACK_EN
Loopback DQS sampling	1	1
Flash DQS sampling	1	0

Serial flash data and clock path for input timing is shown in the following figure.

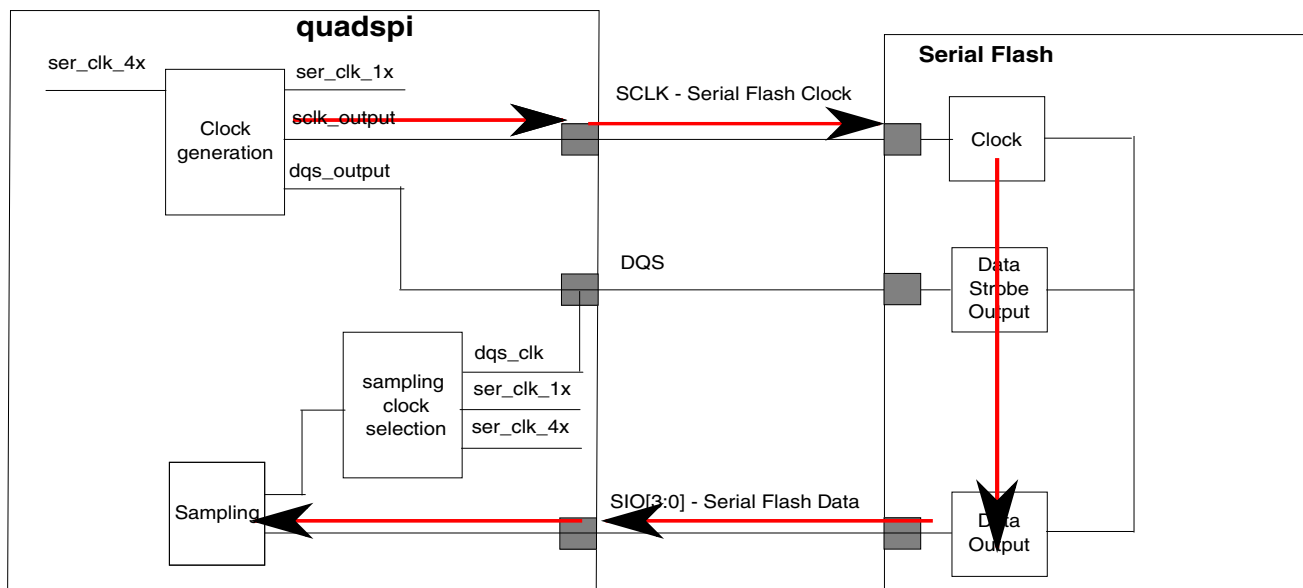

Figure 43-11. Serial flash data and clock path

NOTE

The red line is for data input path, the blue line is for DQS loopback path, and the purple line is for DQS input path from Serial Flash.

Total delay ($T_{total_delay_data}$) for serial flash data input is the sum of following delay:

1. Output delay of serial flash clock from internal serial clock to SCLK pad inside SOC
2. Wire delay of serial flash clock (SCLK) from SOC to external Serial Flash Device
3. Clock to Output Valid time of external Serial Flash Device
4. Wire delay of serial flash data (SIO) from external serial Flash Device to SOC
5. Input delay of serial flash data from SIO pad to internal sample register

Total delay ($T_{total_delay_loopback_dqs}$) for loopback DQS clock is the sum of following delay:

1. Output delay of DQS clock from internal serial clock to DQS pad inside SOC
2. Input delay of DQS clock from DQS pad to internal sample register

Total delay ($T_{total_delay_flash_dqs}$) for Flash DQS clock is the sum of following delay:

1. Output delay of serial flash clock from internal serial clock to SCLK pad inside SOC
2. Wire delay of serial flash clock (SCLK) from SOC to external Serial Flash Device

3. Clock to DQS Output time of external Serial Flash Device
4. Wire delay of serial flash data strobe (DQS) from external serial Flash Device to SOC
5. Input delay of DQS clock from DQS pad to internal sample register

43.10.1 Input timing in SDR mode with internal sampling

Input Timing diagram in SDR mode with internal sampling is show in the figure below.

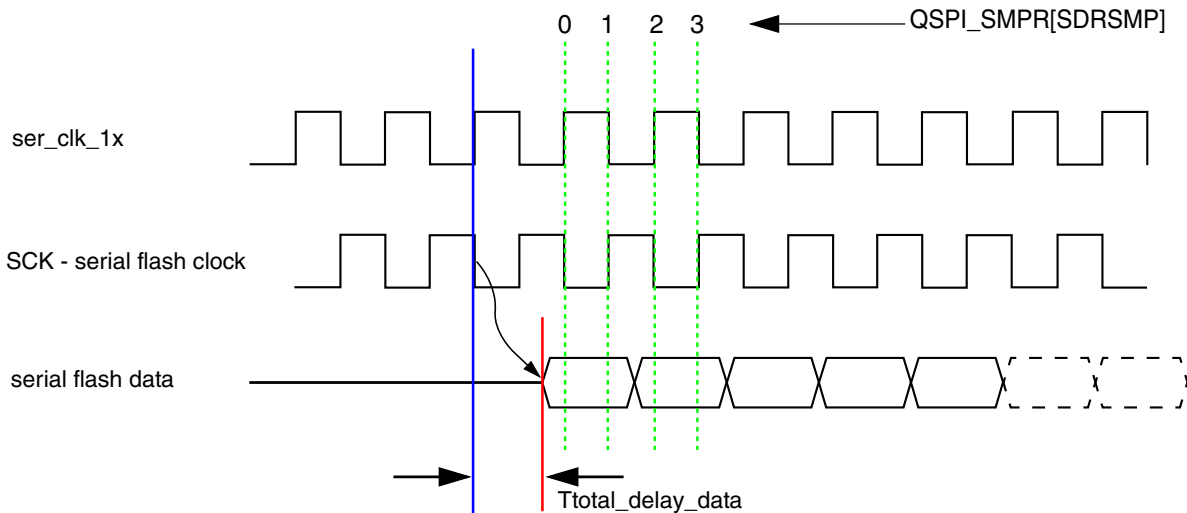

Figure 43-12. Internal sample SDR

There are four sample points for this sampling mode, which is determined by register field `QSPI_SMPR.SDRSMP`.

Sampling point need to be select correctly to meet both Setup and Hold timing for internal sample registers:

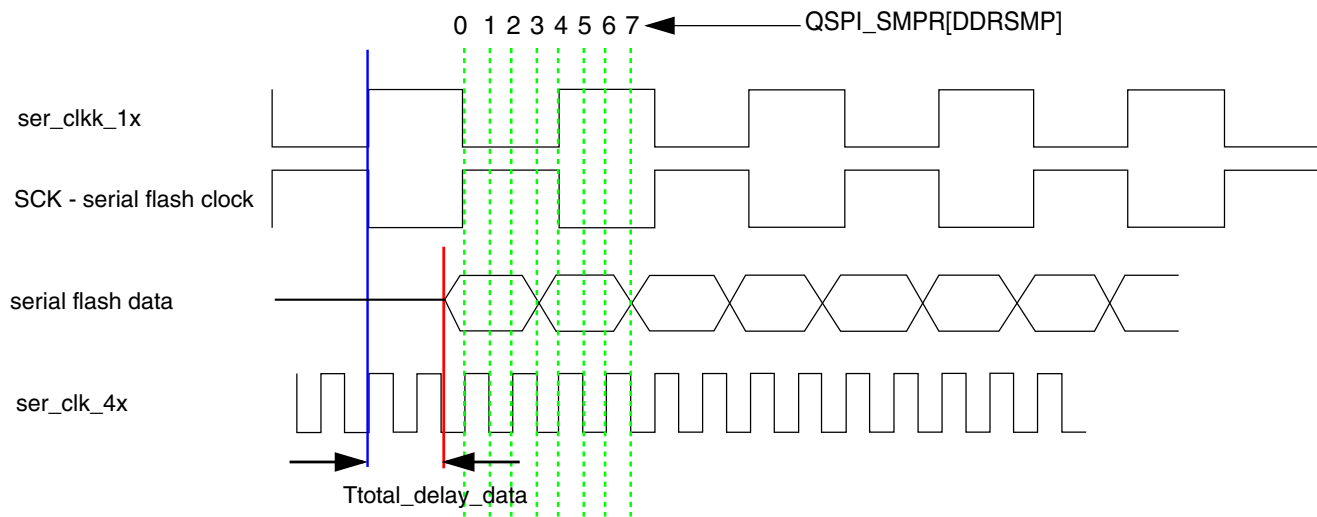

- For sample point N, Setup requirement is: $T_{\text{cycle}} \cdot (N+2)/2 > T_{\text{total_delay_data,max}}$
- For sample point N, Hold requirement is: $T_{\text{total_delay_data,min}} > T_{\text{cycle}} \cdot N/2$

NOTE

T_{cycle} is the cycle of `ser_clk_1x`. $T_{\text{total_delay_data,max}}$ is maximum delay of serial data input path. $T_{\text{total_delay_data,min}}$ is the minimum delay of serial data input path. $N=0,1,2,3$

43.10.2 Input timing in DDR mode with internal sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

There are 8 sample points for this sampling mode, which is determined by register field DDRSMP.

Sampling point need to be select correctly to meet both Setup and Hold timing for internal sample registers:

- For sample point N, Setup requirement is: $T_{cycle} * (N+2)/8 > T_{total_delay_data,max}$
- For sample point N, Hold requirement is: $T_{total_delay_data,min} > T_{cycle} * N/8$

43.10.3 Input timing in SDR mode with loopback DQS sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

Figure 43-13. Input timing in SDR mode with loopback DQS sampling

In SDR mode and loopback sampling mode, DQS_PHASE_EN should be set 1.

For this sample point, the Setup requirement is: $T_{\text{cycle}} > \max(T_{\text{total_delay_data}} - T_{\text{total_delay_loopback_dqs}})$. The Hold requirement is: $\min(T_{\text{total_delay_data}} - T_{\text{total_delay_loopback_dqs}}) > 0$.

43.10.4 Input timing in DDR mode with loopback DQS sampling

Input Timing diagram in DDR mode with internal sampling is show in the following figure.

Figure 43-14. Input timing in DDR mode with loopback DQS sampling

In DDR mode and loopback sampling mode, DQS_PHASE_EN should be set 0.

For this sample point, the Setup requirement is: $T_{cycle} > \max(T_{total_delay_data} - T_{total_delay_loopback_dqs})$. The Hold requirement is: $\min(T_{total_delay_data} - T_{total_delay_loopback_dqs}) > 0$.

43.10.5 Input timing in SDR mode with flash DQS sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

Figure 43-15. Input timing in SDR mode with flash DQS sampling

In this sampling mode, there will be a setup/hold requirement on Flash serial Data and Flash serial Data Strobe. This value will be specified in the data sheet.

43.10.6 Input timing in DDR mode with flash DQS sampling

Input Timing diagram in DDR mode with internal sampling is show in the following figure.

Figure 43-16. Input timing in DDR mode with flash DQS sampling

In this sampling mode, there will be a setup/hold requirement on Flash serial Data and Flash serial Data Strobe. This value will be specified in the data sheet.

43.10.7 Data Strobe Signal functionality

Some external serial flashes provide the data strobe (DQS/RDS) output which is fed directly to the QuadSPI module. The strobe (DQS/RDS) signal needs to be delayed to have the edges aligned to the data valid period. QuadSPI internally samples the incoming data at posedge of the strobe signal for SDR and on both the edges of the strobe signal for DDR. Refer to the figure for more detail.

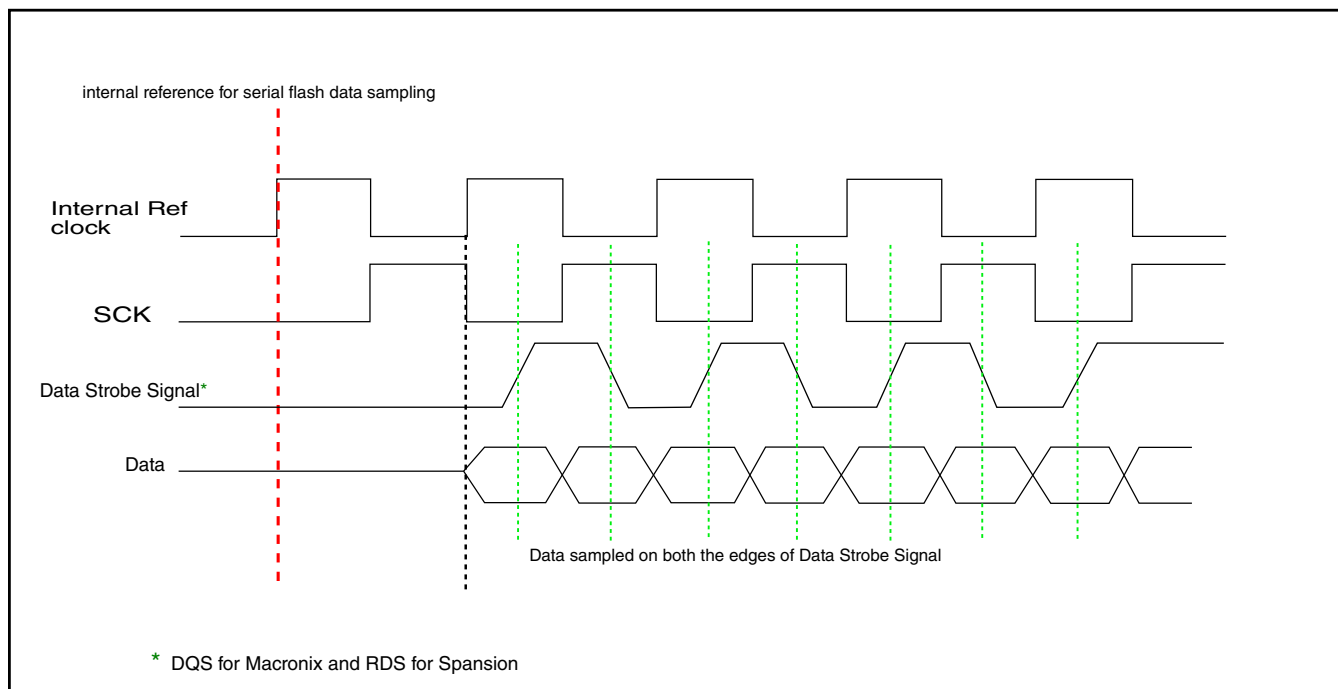

Figure 43-17. Data strobe signal functionality

43.11 Output timing in SDR mode

Output timing diagram in SDR mode is show in the following figure.

Figure 43-18. Output timing in SDR mode

In SDR mode, quadspi output serial data with internal serial clock rise edge 1x (`ser_clk_1x`). Flash Device has requirement on Data and Clock setup and hold timing.

43.12 Output timing in DDR mode

Output Timing diagram in DDR mode is show in the following figure.

Figure 43-19. Output timing in DDR mode

In DDR mode, quadspi output serial data with internal serial clock both edge 1x (`ser_clk_1x`) and then delay one `ser_clk_4x` cycle for hold timing.

NOTE

TX_DDR_DELAY_EN should be set to 1 for DDR mode.

43.13 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

43.13.1 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

NOTE

See the System Memory map in this document for the base address of the QSPI AHB RX Data Buffer.

memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
0	AHB RX Data Buffer register (ARDB0)	32	R/W	0000_0000h	43.13.1.1/2818
4	AHB RX Data Buffer register (ARDB1)	32	R/W	0000_0000h	43.13.1.1/2818

43.13.1.1 AHB RX Data Buffer register (ARDBn)

The AHB RX Data Buffer register 0 to 31 can be used to read the buffer content of the RX Buffer from successive addresses. QSPI_ARDB0 corresponds to the RX Buffer register entry corresponding to the current value of the read pointer with increasing order.

The increment of the read pointer depends from the access scheme (DMA or flag-driven). Refer to "Data Transfer from the QuadSPI Module Internal Buffers" section in [Flash Read](#) section, RX Buffer, data read via register interface and AHB read, for the description of successive accesses to the RX Buffer content. Refer also to [Byte Ordering of Serial Flash Read Data](#) for the byte ordering scheme.

Valid address range accessible in the QSPI_ARDBn range depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

- Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QSPI_ARDB0 to QSPI_ARDB31.
- Example 2, RX Buffer filled with 5 valid words, RX Buffer fill level QSPI_RBSR[RDBFL] is 5. In this case an access to QSPI_ARDB4 provides the last valid entry.

Address: 0h base + 0h offset + (4d × i), where i=0d to 31d

ARDBn field descriptions

Field	Description
ARXD	ARDB provided RX Buffer Data. Byte order (endianness) is identical to the RX Buffer Data Registers.

43.14 Peripheral Bus Register Descriptions

This section provides the peripheral bus register information of the QuadSPI module.

This section provides the memory map and register definitions of the QuadSPI module.

QuadSPI_MCR field descriptions

Field	Description
31 Reserved	This field is reserved. This field should always be set to 0.
30 DQS_PHASE_EN	This bit controls internal DQS output phase. If DQS_EN and DQS_LOOPBACK_EN are both set to 1, this bit should be set in SDR mode, and cleared in DDR mode. If either DQS_EN or DQS_LOOPBACK_EN is set to 0, this bit is ignored.
29 Reserved	This field is reserved. This field should always be set to 0.
28–25 Reserved	This field is reserved. This field should always be set to 0.
24 DQS_LOOPBACK_EN	Quadspi will output serial data strobe signal which will be loopback from pad to sample input flash serial data. Please note pad should be force input for loopback. Quadspi will output serial data strobe signal which will be loopback from pad to sample input flash serial data. Please note pad should be force input for loopback. This bit is a don't care when DQS_EN is set to 0. 1'b1 DQS loopback sampling enabled 1'b0 DQS loopback sampling disabled
23–20 Reserved	This field is reserved.
19–16 Reserved	This field is reserved. This field is reserved and should always be set to 0xF.
15 Reserved	This field is reserved. This field is reserved.
14 MDIS	Module Disable. The MDIS bit allows the clock to the non-memory mapped logic in the QuadSPI to be stopped, putting the QuadSPI in a software controlled power-saving state. Please refer to , for more information.

Table continues on the next page...

QuadSPI_MCR field descriptions (continued)

Field	Description
	0 Enable QuadSPI clocks. 1 Allow external logic to disable QuadSPI clocks.
13–12 Reserved	This field is reserved.
11 CLR_TXF	Clear TX FIFO/Buffer. Invalidate the TX Buffer content. 0 No action. 1 Read and write pointers of the TX Buffer are reset to 0. QSPI_TBSR[TRCTR] is reset to 0.
10 CLR_RXF	Clear RX FIFO. Invalidate the RX Buffer. 0 No action. 1 Read and write pointers of the RX Buffer are reset to 0. QSPI_RBSR[RDBFL] is reset to 0.
9–8 Reserved	This field is reserved.
7 DDR_EN	DDR mode enable: 0 2x and 4x clocks are disabled for SDR instructions only 1 2x and 4x clocks are enabled supports both SDR and DDR instruction.
6 DQS_EN	DQS enable: This field is valid for both SDR and DDR mode. For more details Refer Data Strobe Signal Functionality 0 DQS disabled. 1 DQS enabled- When enabled, the incoming data is sampled on both the edges of DQS input when QSPI_MCR[DDR_EN] is set, else, on only one edge when QSPI_MCR[DDR_EN] is 0. The QSPI_SMPR[DDR_SMP] values are ignored.
5–4 Reserved	This field is reserved.
3–2 END_CFG	Defines the endianness of the QSPI module. For more details refer to Byte Ordering Endianness
1 SWRSTHD	Software reset for AHB domain NOTE: Please keep other fields value when write to SWRSTHD and SWRSTSD NOTE: These software reset don't reset register setting but only reset internal flip-flops in quadspi controller NOTE: To remove the reset, need to write 0 to SWRSTHD and SWRSTSD 0 No action 1 AHB domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.
0 SWRSTSD	Software reset for Serial Flash domain NOTE: Please keep other fields value when write to SWRSTHD and SWRSTSD NOTE: These software reset don't reset register setting but only reset internal flip-flops in quadspi controller NOTE: To remove the reset, need to write 0 to SWRSTHD and SWRSTSD

Table continues on the next page...

QuadSPI_MCR field descriptions (continued)

Field	Description
0	No action
1	Serial Flash domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.

43.14.2 IP Configuration Register (QuadSPI_IPCR)

The IP configuration register provides all the configuration required for an IP initiated command. An IP command can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash is started as per the sequence pointed to by the SEQID field. Refer to [Normal Mode](#), for details about the command triggering and command execution.

Write:

- $QSPI_SR[IP_ACC]=0$

Address: 21E_0000h base + 8h offset = 21E_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved				SEQID				Reserved							PAR_EN
W	Reserved				SEQID				Reserved							PAR_EN

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	IDATSZ															
W	IDATSZ															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPI_IPCR field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27–24 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table for more details. A write to this bit -field triggers a transaction on the serial flash interface.
23–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
IDATSZ	IP data transfer size: Defines the data transfer size in bytes of the IP command.

43.14.3 Flash Configuration Register (QuadSPI_FLSHCR)

The Flash configuration register contains the flash device specific timings that must be met by the QuadSPI controller for the device to function correctly.

Write:

- $QSPI_SR[AHB_ACC] = 0$
- $QSPI_SR[IP_ACC] = 0$

Address: 21E_0000h base + Ch offset = 21E_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																TCSH			Reserved			TCSS									
W	Reserved																TCSH			Reserved			TCSS									
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1

QuadSPI_FLSHCR field descriptions

Field	Description
31–12 Reserved	This field is reserved. Reserved.
11–8 TCSH	Serial flash CS hold time in terms of serial flash clock cycles. NOTE: The actual delay between chip select assertion and clock fall edge is defined as: <ul style="list-style-type: none"> • 1 SCK cycle if TCSH is set 0 or 1 • N SCK cycle if TCSH is set N (N>1)
7–4 Reserved	This field is reserved. Reserved.
TCSS	Serial flash CS setup time in terms of serial flash clock cycles. NOTE: <ol style="list-style-type: none"> 1. The actual delay between chip select assertion and clock fall edge is defined as: <ul style="list-style-type: none"> • 0.5 SCK cycle if TCSS is set 0 or 1 • N+0.5 SCK cycle if TCSS is set N (N>1) 2. Any update to TCSS register bits is visible on the flash interface only from the second transaction following the update.

43.14.4 Buffer0 Configuration Register (QuadSPI_BUF0CR)

This register provides the configuration for any access to buffer0. An access is routed to buffer0 when the master port number of the incoming AHB request matches the MSTRID field of the BUF0CR. Any buffer "miss" leads to a serial flash transaction being triggered as per the sequence pointed to the SEQID field. Buffer0 may also be configured as a high priority buffer by setting the HP_EN field of this register.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: 21E_0000h base + 10h offset = 21E_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R																
W	HP_EN	Reserved														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ADATSZ								Reserved				MSTRID			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPI_BUF0CR field descriptions

Field	Description
31 HP_EN	High Priority Enable: When set, the master associated with this buffer is assigned a priority higher than the rest of the masters. An access by a high priority master will suspend any ongoing prefetch by another AHB master and will be serviced on high priority. Refer to Flexible AHB Buffers for details.
30–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER0. Any AHB access with this master port number is routed to this buffer.

43.14.5 Buffer1 Configuration Register (QuadSPI_BUF1CR)

This register provides the configuration for any access to buffer1. An access is routed to buffer1 when the master port number of the incoming AHB request matches the MSTRID field of the BUF1CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: 21E_0000h base + 14h offset = 21E_0014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	Reserved																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPI_BUF1CR field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER1. Any AHB access with this master port number is routed to this buffer.

43.14.6 Buffer2 Configuration Register (QuadSPI_BUF2CR)

This register provides the configuration for any access to buffer2. An access is routed to buffer2 when the master port number of the incoming AHB request matches the MSTRID field of the BUF2CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: 21E_0000h base + 18h offset = 21E_0018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

QuadSPI_BUF2CR field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER2. Any AHB access with this master port number is routed to this buffer.

43.14.7 Buffer3 Configuration Register (QuadSPI_BUF3CR)

This register provides the configuration for any access to buffer3. An access is routed to buffer3 when the master port number of the incoming AHB request matches the MSTRID field of the BUF3CR. Any buffer "miss" leads to the buffer being flushed a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the ALLMST field is set, any transaction where the master port number does not match any of the buffer MSTRID fields will be routed to this buffer. In the case that the ALLMST field is not set, any such transaction (where master port number does not match any of the MSTRID fields) will be returned an ERROR response.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: 21E_0000h base + 1Ch offset = 21E_001Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W	ALLMST

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPI_BUF3CR field descriptions

Field	Description
31 ALLMST	All master enable: When set, buffer3 acts as an all-master buffer. Any AHB access with a master port number not matching with the master ID of buffer0 or buffer1 or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored.
30–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER3. Any AHB access with this master port number is routed to this buffer.

43.14.8 Buffer Generic Configuration Register (QuadSPI_BFGENCR)

This register provides the generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the PAR_EN field is set, all the buffer accesses result in parallel accesses to the flashes.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: 21E_0000h base + 20h offset = 21E_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

QuadSPI_BFGENCR field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
15–12 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table . NOTE: If the sequence pointer differs between the new and previous sequence then the user should reset this. See QSPI_SPTRCLR for more information.
Reserved	This field is reserved.

43.14.9 Buffer0 Top Index Register (QuadSPI_BUF0IND)

This register specifies the top index of buffer0, which defines its size. Note that that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned, as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less 8. For example, setting BUF0IND to 0 gives 8 bytes, 1 give 16bytes etc.

The size of buffer0 is the difference between the BUF0IND+8 and 0.

It is the responsibility of the software to ensure that BUF0IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: 21E_0000h base + 30h offset = 21E_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPI_BUF1IND field descriptions

Field	Description
31–3 TPINDX1	Top index of buffer 1.
Reserved	This field is reserved.

43.14.11 Buffer2 Top Index Register (QuadSPI_BUF2IND)

This register specifies the top index of buffer2, which defines its size. Note that that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less 8. The size of buffer2 is the difference between the BUF2IND and BUF1IND.

It is the responsibility of the software to ensure that BUF2IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: 21E_0000h base + 38h offset = 21E_0038h

QuadSPI_BUF2IND field descriptions

Field	Description
31–3 TPINDX2	Top index of buffer 2.
Reserved	This field is reserved.

43.14.12 Serial Flash Address Register (QuadSPI_SFAR)

The module automatically translates this address on the memory map to the address on the flash itself. When operating in 24bit mode, only bits 23-0 are sent to the flash, in 32bit mode, bits 27-0 are used with bits 31-28 driven to 0. Refer to [Table 43-5](#) for the mapping between the access mode and the QSPI_SFAR content and to [Normal Mode](#) for details about the command triggering and command execution. The software should ensure that the serial flash address provided in the QSPI_SFAR register lies in the valid flash address range as defined in [Table 43-5](#).

Write:

- $QSPI_SR[IP_ACC] = 0$

Address: 21E_0000h base + 100h offset = 21E_0100h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPI_SMPR field descriptions

Field	Description
31–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 DDRSMP	DDR Sampling point. Select the sampling point for incoming data when serial flash is executing a DDR instruction. Refer to Input timing in DDR mode with internal sampling , for details on the sampling points.
15–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–5 SDRSMP	SDR sampling point.
4–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

43.14.14 RX Buffer Status Register (QuadSPI_RBSR)

This register contains information related to the receive data buffer.

Address: 21E_0000h base + 10Ch offset = 21E_010Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

QuadSPI_RBSR field descriptions

Field	Description
31–16 RDCTR	Read Counter, indicates how many entries of 4 bytes have been removed from the RX Buffer. For example a value of 0x2 would indicate 8bytes have been removed It is incremented by the number (QSPI_RBCT[WMRK] + 1) on RX Buffer POP event. The RX Buffer can be popped using DMA or pop flag QSPI_FR[RBDF]. The QSPI_RSER[RBDE] defines which pop has to be done. For further details please refer to AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31) and "Data Transfer from the QuadSPI Module Internal Buffers" section in Flash Read section.
15–14 Reserved	This field is reserved.
13–8 RDBFL	RX Buffer Fill Level, indicates how many entries of 4 bytes are still available in the RX Buffer. For example a value of 0x2 would indicate 8bytes are available.
Reserved	This field is reserved.

43.14.15 RX Buffer Control Register (QuadSPI_RBCT)

This register contains control data related to the receive data buffer.

Write:

- $QSPI_SR[IP_ACC] = 0$

Address: 21E_0000h base + 110h offset = 21E_0110h

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16
R	Reserved																
W	Reserved																
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

W	Reserved								Reserved			WMRK					
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

QuadSPI_RBCT field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 RXBRD	<p>RX Buffer Readout: This bit specifies the access scheme for the RX Buffer readout.</p> <p>0 RX Buffer content is read using the AHB Bus registers QSPI_ARDB0 to QSPI_ARDB31. For details, refer to Exclusive Access to Serial Flash for AHB Commands.</p> <p>1 RX Buffer content is read using the IP Bus registers QSPI_RBDR0 to QSPI_RBDR31.</p>
7–5 Reserved	This field is reserved.
WMRK	<p>RX Buffer Watermark: This field determines when the readout action of the RX Buffer is triggered. When the number of valid entries in the RX Buffer is equal to or greater than the number given by (WMRK+1) the QSPI_SR[RXWE] flag is asserted. The value should be entered as the number of 4byte entries minus 1. For example a value of 0x0 would set the watermark to 4bytes, 1 to 8bytes, 2 to 12bytes etc.</p> <p>For details, refer to DMA Usage.</p>

43.14.16 TX Buffer Status Register (QuadSPI_TBSR)

This register contains information related to the transmit data buffer.

Address: 21E_0000h base + 150h offset = 21E_0150h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	Reserved																Reserved			Reserved				Reserved								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPI_TBSR field descriptions

Field	Description
31–16 TRCTR	Transmit Counter. This field indicates how many entries of 4 bytes have been written into the TX Buffer by host accesses. It is reset to 0 when a 1 is written into the QSPI_MCR[CLR_TXF] bit. It is incremented on each write access to the QSPI_TBDR register when another word has been pushed onto the TX Buffer. When it is not cleared the TRCTR field wraps around to 0. Refer to TX Buffer Data Register (QuadSPI_TBDR) for details.
15–13 Reserved	This field is reserved.
12–8 TRBFL	TX Buffer Fill Level. The TRBFL field contains the number of entries of 4 bytes each available in the TX Buffer for the QuadSPI module to transmit to the serial flash device.
Reserved	This field is reserved.

43.14.17 TX Buffer Data Register (QuadSPI_TBDR)

The QSPI_TBDR register provides access to the circular TX Buffer of depth 128 bytes. This buffer provides the data written into it as write data for the page programming commands to the serial flash device. Refer to [Table 43-14](#) for the byte ordering scheme. A write transaction on the flash with data size of less than 32 bits will lead to the removal of four data entry from the TX buffer. The valid bits will be used and the rest of the bits will be discarded.

Write:

- $QSPI_SR[TXFULL] = 0$

32-bit write access required

NOTE

There is no limitation on Flash programming size. But the data size written to TX Buffer should be 64 Byte aligned. If flash programming size is not 64 bytes aligned, please write redundant data to TX Buffers. The redundant data will be ignored by QuadSPI controller.

Address: 21E_0000h base + 154h offset = 21E_0154h

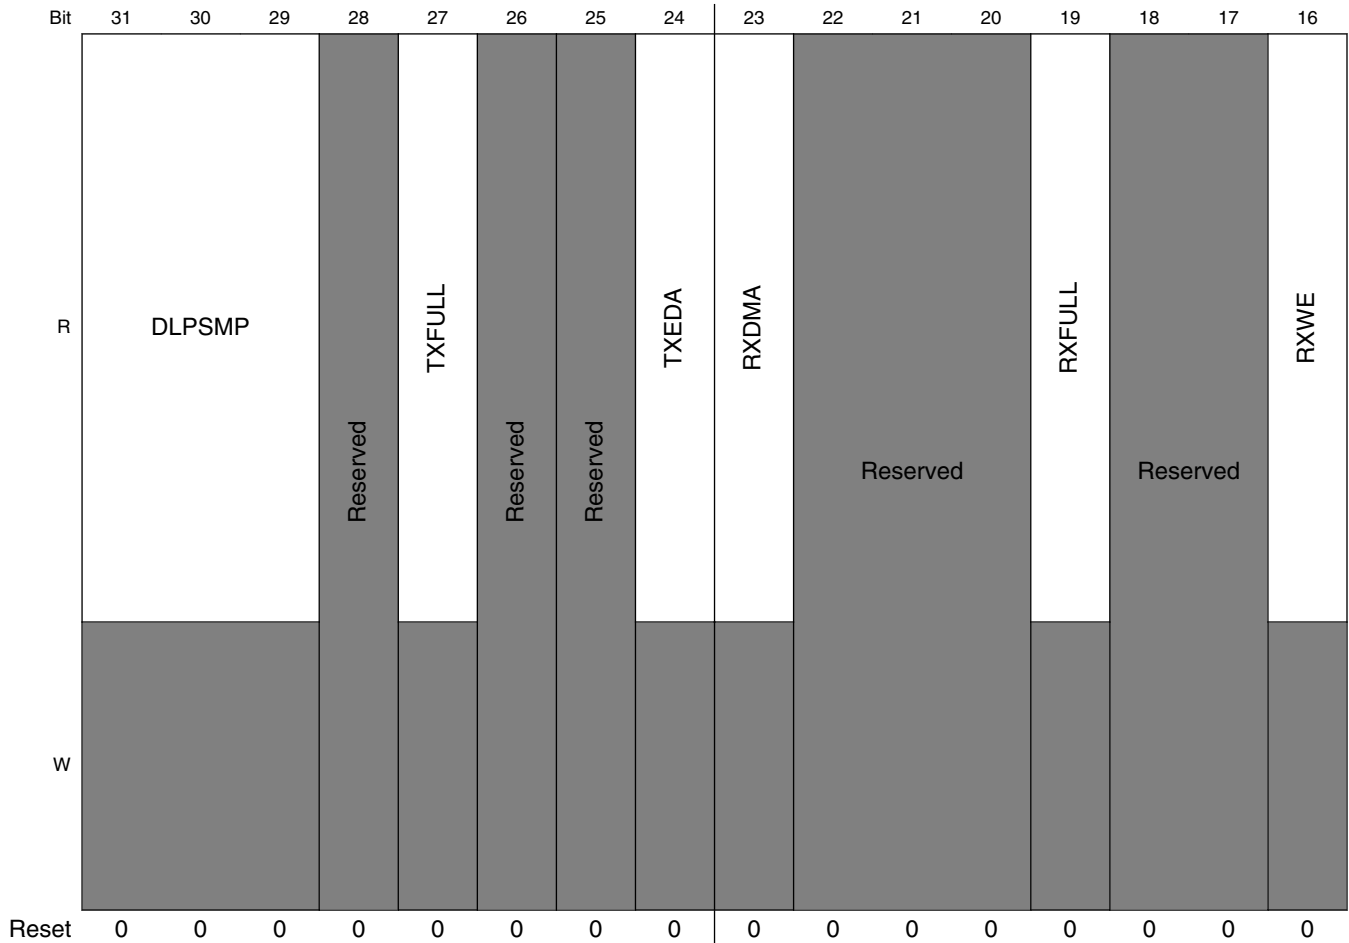

**QuadSPI_TBDR field descriptions**

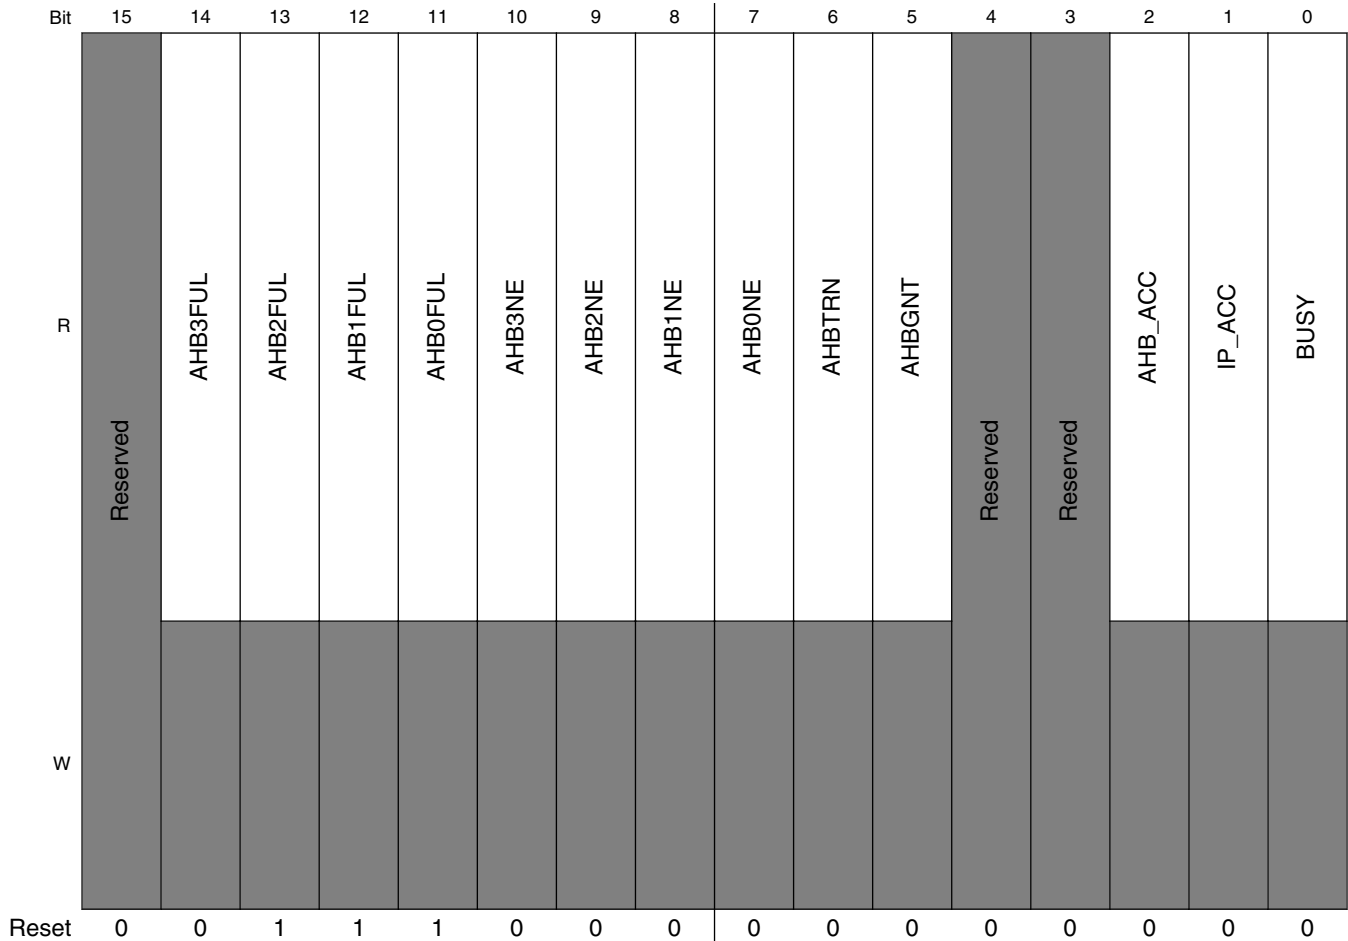

Field	Description
TXDATA	<p>TX Data</p> <p>On write access the data is written into the next available entry of the TX Buffer and the QPSI_TBSR[TRBFL] field is updated accordingly.</p> <p>On a read access, the last data written to the register is returned.</p>

43.14.18 Status Register (QuadSPI_SR)

The QSPI_SR register provides all available status information about SFM command execution and arbitration, the RX Buffer and TX Buffer and the AHB Buffer.

Address: 21E_0000h base + 15Ch offset = 21E_015Ch

QuadSPI_SR field descriptions

Field	Description
31–29 DLPSMP	<p>NOTE: Data learning is not implemented on this chip. Data learning pattern sampling point: The sampling point found by the controller with the data learning pattern.</p> <ul style="list-style-type: none"> This is used for DDR only. If the learning fails, this field will return garbage and DLPFF bit will be set.
28 Reserved	This field is reserved.
27 TXFULL	TX Buffer Full: Asserted when no more data can be stored.
26 Reserved	This field is reserved.
25 Reserved	This field is reserved.
24 TXEDA	<p>Tx Buffer Enough Data Available</p> <p>Asserted when TX Buffer contains enough data for any pop operation to take place. There must be atleast 128bit data available in TX FIFO for any pop operation otherwise QSPI_FR[TBUF] will be set.</p>

Table continues on the next page...

QuadSPI_SR field descriptions (continued)

Field	Description
23 RXDMA	RX Buffer DMA: Asserted when RX Buffer read out via DMA is active i.e DMA is requested or running.
22–20 Reserved	This field is reserved.
19 RXFULL	RX Buffer Full: Asserted when the RX Buffer is full, i.e. that QSPI_RBSR[RDBFL] field is equal to 32.
18–17 Reserved	This field is reserved.
16 RXWE	RX Buffer Watermark Exceeded: Asserted when the number of valid entries in the RX Buffer exceeds the number given in the QSPI_RBCT[WMRK] field.
15 Reserved	This field is reserved.
14 AHB3FUL	AHB 3 Buffer Full: Asserted when AHB 3 buffer is full.
13 AHB2FUL	AHB 2 Buffer Full: Asserted when AHB 2 buffer is full.
12 AHB1FUL	AHB 1 Buffer Full: Asserted when AHB 1 buffer is full.
11 AHB0FUL	AHB 0 Buffer Full: Asserted when AHB 0 buffer is full.
10 AHB3NE	AHB 3 Buffer Not Empty: Asserted when AHB 3 buffer contains data.
9 AHB2NE	AHB 2 Buffer Not Empty: Asserted when AHB 2 buffer contains data.
8 AHB1NE	AHB 1 Buffer Not Empty: Asserted when AHB 1 buffer contains data.
7 AHB0NE	AHB 0 Buffer Not Empty: Asserted when AHB 0 buffer contains data.
6 AHBTRN	AHB Access Transaction pending: Asserted when there is a pending request on the AHB interface. Refer to the AMBA specification for details.
5 AHBGNT	AHB Command priority Granted: Asserted when another module has been granted priority of AHB Commands against IP Commands. For details refer to Command Arbitration .
4 Reserved	This field is reserved.
3 RESERVED	This field is reserved.
2 AHB_ACC	AHB Access: Asserted when the transaction currently executed was initiated by AHB bus.
1 IP_ACC	IP Access: Asserted when transaction currently executed was initiated by IP bus.
0 BUSY	Module Busy: Asserted when module is currently busy handling a transaction to an external flash device.

43.14.19 Flag Register (QuadSPI_FR)

The QSPI_FR register provides all available flags about SFM command execution and arbitration which may serve as source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash device itself but only to the behavior and conditions visible in the QuadSPI module.

Write: Enabled Mode

Address: 21E_0000h base + 160h offset = 21E_0160h

QuadSPI_FR field descriptions

Field	Description
31 DLFFF	NOTE: Data learning is not implemented on this chip. Data Learning Pattern Failure Flag: Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern. The controller automatically starts sampling using the value in QSPI_SMPR[DDRSMP].
30 Reserved	This field is reserved.
29–28 Reserved	This field is reserved.
27 TBFF	TX Buffer Fill Flag: Before writing to the TX buffer, this bit should be cleared. Then this bit has to be read back. If the bit is set, the TX Buffer can take more data. If the bit remains cleared, the TX buffer is full. Refer to Tx Buffer Operation for details.
26 TBUF	TX Buffer Underrun Flag: Set when the module tried to pull data although TX Buffer was empty or the buffer contains less than 128 bits of data. The application must ensure that the buffer never goes empty during a transaction except for the last data fetch. The IP Command leading to the TX Buffer underrun is continued (data sent to the serial flash device is all F in case of valid tx underrun). The application must clear the TX Buffer in response to this event by writing a 1 into the QSPI_MCR[CLR_TXF] bit.
25–24 Reserved	This field is reserved.
23 ILLINE	Illegal Instruction Error Flag: Set when an illegal instruction is encountered by the controller in any of the sequences. Refer to Table 43-12 for a list of legal instructions.
22–18 Reserved	This field is reserved.
17 RBOF	RX Buffer Overflow Flag: Set when not all the data read from the serial flash device could be pushed into the RX Buffer. The IP Command leading to this condition is continued until the number of bytes according to the QSPI_IPCR[IDATSZ] field has been read from the serial flash device.

Table continues on the next page...

QuadSPI_FR field descriptions (continued)

Field	Description
	The content of the RX Buffer is not changed.
16 RBDF	<p>RX Buffer Drain Flag: Will be set if the QuadSPI_SR[RXWE] status bit is asserted.</p> <p>Writing 1 into this bit triggers one of the following actions:</p> <ul style="list-style-type: none"> • If the RX Buffer has up to QuadSPI_RBCT[WMRK] valid entries then the flag is cleared. • If the RX Buffer has more than QuadSPI_RBCT[WMRK] valid entries and the QuadSPI_RSER[RBDDE] bit is not set (flag driven mode) a RX Buffer POP event is triggered. <p>The flag remains set if the RX Buffer contains more than QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished.</p> <p>The flag is cleared if the RX Buffer contains less than or equal to QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished.</p> <p>Refer to "Receive Buffer Drain Interrupt or DMA Request" section in Normal Mode Interrupt and DMA Requests, for details.</p>
15 ABSEF	<p>AHB Sequence Error Flag: Set when the execution of an AHB Command is started with an WRITE or WRITE_DDR Command in the sequence pointed to by the QSPI_BUFxCR register</p> <p>Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module.</p> <p>The AHB bus request which triggered this command is answered with an ERROR response.</p>
14 Reserved	<p>Reserved</p> <p>This field is reserved.</p>
13 Reserved	<p>Reserved</p> <p>This field is reserved.</p>
12 ABOF	<p>AHB Buffer Overflow Flag: Set when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if the QSPI_BUFxCR[ADATSZ] field is programmed incorrectly.</p> <p>The AHB Command leading to this condition is continued until the number of entries according to the QSPI_BUFxCR[ADATSZ] field has been read from the serial flash device.</p> <p>The content of the AHB Buffer is not changed.</p>
11 IUEF	<p>IP Command Usage Error Flag: Set when in parallel flash mode the execution of an IP Command is started and the sequence pointed to by the sequence ID contains a WRITE or a WRITE_DDR command. Refer to Table 43-12 table for the related commands.</p> <p>Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module.</p>
10–8 Reserved	This field is reserved.
7 IPAIEF	<p>IP Command Trigger during AHB Access Error Flag. Set when the following condition occurs:</p> <ul style="list-style-type: none"> • A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHB_ACC] bit is set. Any command leading to the assertion of the IPAIEF flag is ignored.
6 IPIEF	<p>IP Command Trigger could not be executed Error Flag. Set when the QSPI_SR[IP_ACC] bit is set (i.e. an IP triggered command is currently executing) and any of the following conditions occurs:</p> <ul style="list-style-type: none"> • Write access to the QSPI_IPCR register. Any command leading to the assertion of the IPIEF flag is ignored • Write access to the QSPI_SFAR register. • Write access to the QSPI_RBCT register.
5 Reserved	This field is reserved.

Table continues on the next page...

QuadSPI_FR field descriptions (continued)

Field	Description
4 IPGEF	IP Command Trigger during AHB Grant Error Flag: Set when the following condition occurs: <ul style="list-style-type: none"> A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHBGNT] bit is set. Any command leading to the assertion of the IPGEF flag is ignored.
3–1 Reserved	This field is reserved.
0 TFF	IP Command Transaction Finished Flag: Set when the QuadSPI module has finished a running IP Command. If an error occurred the related error flags are valid, at the latest, in the same clock cycle when the TFF flag is asserted.

1. QSPI_BUFxCR implies anyone of QSPI_BUF0CR/QSPI_BUF1CR/QSPI_BUF2CR/QSPI_BUF3CR

43.14.20 Interrupt and DMA Request Select and Enable Register (QuadSPI_RSER)

The QuadSPI_RSER register provides enables and selectors for the interrupts in the QuadSPI module.

NOTE

Each flag of the QuadSPI_FR register enabled as source for an interrupt prevents the QuadSPI module from entering Stop Mode or Module Disable Mode when this flag is set.

Write: Anytime

Address: 21E_0000h base + 164h offset = 21E_0164h

QuadSPI_SPNDST field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–9 DATLFT	Data left: Provides information about the amount of data left to be read in the suspended sequence. Valid only when SUSPND is set to 1'b1. Value in terms of 64 bits or 8 bytes
8 Reserved	This field is reserved.
7–6 SPDBUF	Suspended Buffer: Provides the suspended buffer number. Valid only when SUSPND is set to 1'b1
5–1 Reserved	This field is reserved.
0 SUSPND	When set, it signifies that a sequence is in suspended state

43.14.22 Sequence Pointer Clear Register (QuadSPI_SPTRCLR)

The sequence pointer clear register provides bits to reset the IP and Buffer sequence pointers. The sequence pointer contains the index of which instruction within the LUT entry is to be executed next. For example, if the LUT entry ends on a JMP_ON_CS value of 2, the index will be stored as 2.

The software should reset the sequence pointers whenever the sequence ID is changed by updating the SEQID field in QSPI_IPCR or QSPI_BFGENCR.

Address: 21E_0000h base + 16Ch offset = 21E_016Ch

Address: 21E_0000h base + 18Ch offset = 21E_018Ch

QuadSPI_SFB2AD field descriptions

Field	Description
31–10 TPADB2	Top address for Serial Flash B2. In effect, TPxxAD is the first location of the next memory.
Reserved	This field is reserved.

43.14.27 RX Buffer Data Register (QuadSPI_RBDRn)

The QuadSPI_RBDR registers provide access to the individual entries in the RX Buffer. Refer to [Table 43-14](#) for the byte ordering scheme.

QuadSPI_RBDR0 corresponds to the actual position of the read pointer within the RX Buffer. The number of valid entries available depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QuadSPI_RBDR0 to QuadSPI_RBDR31.

Example 2, RX Buffer filled with 5 valid words: RX Buffer fill level QuadSPI_RBSR[RDBFL] is 5. In this case an access to QuadSPI_RBDR4 provides the last valid entry.

Any access beyond the range of valid RX Buffer entries provides undefined results.

Address: 21E_0000h base + 200h offset + (4d × i), where i=0d to 31d

QuadSPI_RBDRn field descriptions

Field	Description
RXDATA	RX Data. The RXDATA field contains the data associated with the related RX Buffer entry. Data format and byte ordering is given in Byte Ordering of Serial Flash Read Data .

43.14.28 LUT Key Register (QuadSPI_LUTKEY)

The LUT Key register contains the key to lock and unlock the Look-up-table. Refer to [Look-up Table](#) for details.

Write:Anytime

Address: 21E_0000h base + 300h offset = 21E_0300h

QuadSPI_LUTKEY field descriptions

Field	Description
KEY	The key to lock or unlock the LUT. The KEY is 0x5AF05AF0. The read value is always 0x5AF05AF0

43.14.29 LUT Lock Configuration Register (QuadSPI_LCKCR)

The LUT lock configuration register is used along with QSPI_LUTKEY register to lock or unlock the LUT. This register has to be written immediately after QSPI_LUTKEY register for the lock or unlock operation to be successful. Refer to [Look-up Table](#) for details. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

Write: Just after writing the LUT Key Register

(QSPI_LUTKEY)

Address: 21E_0000h base + 304h offset = 21E_0304h

1 UNLOCK	Unlocks the LUT when the following two conditions are met: <ol style="list-style-type: none"> 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key
0 LOCK	Locks the LUT when the following condition is met: <ol style="list-style-type: none"> 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key

43.14.30 Look-up Table register (QuadSPI_LUT0)

The LUT registers are a look-up-table for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash transaction. There are a total of 64 LUT registers. These 64 registers are divided into groups of 4 registers that make a valid sequence. Therefore, QSPI_LUT[0], QSPI_LUT[4], QSPI_LUT[8] QSPI_LUT[60] are the starting registers of a valid sequence. Each of these sets of 4 registers can have a maximum of 8 instructions. A maximum of 16 sequences can be defined at one time. [Look-up Table](#) describes the LUT registers in detail.

Write: Once the LUT is unlocked

Address: 21E_0000h base + 310h offset = 21E_0310h

Chapter 44

ROM Controller with Patch (ROMC)

44.1 Overview

The Read Only Memory Controller with ROM Patch (ROMC) acts as an interface between the ARM advanced high-performance bus (AHB - Lite) and the Read Only Memory. The ROMC consists of a ROM Controller and a ROM Patch. The ROM Patch is used to either patch code routines or fix data tables in the ROM area. There is an IP Bus interface to access the ROM Patch Registers. The following figure depicts the main functional sub-blocks of the ROMC.

Figure 44-1. ROMC Block Diagram

44.1.1 Features

- Supports ROM size ranges from 16 Kbyte up to 4 Mbyte with increments of 1 Kbyte
- Supports opcode patching for a maximum of 16 different addresses in 4 Mbytes of ROM space
- Supports one-word data fixes for a max of 8 memory locations in 4 Mbytes of ROM space
- Supports patching of the Reset Vector (at 0x0000_0000) to allow external booting

44.1.2 Modes of Operation

There are two modes of operation: normal mode and BIST mode. In normal mode, the ROMC ensures correct reads from the ROM, assuming the memory complies with the characteristics and requirements for which the ROMC was designed.

44.1.2.1 Low Power Mode

There are two clock enables that are used to switch off parts of the ROMC logic when inactive. The first clock enable is used to disable the ROM Controller when the master connected to the AHB interface is not initiating a read to the ROM. The second clock enable is used to disable the registers used to program the ROM patch feature when the registers are not being accessed.

44.2 Clocks

The table found here describes the clock sources for ROMCP.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 44-1. ROMCP Clocks

Clock name	Clock Root	Description
hclk	ahb_clk_root	System / bus clock
hclk_reg	ipg_clk_root	System access clock
96krom_CLK	ahb_clk_root	ROM clock

44.3 Memory Map

44.3.1 ROM Memory Map in detail

The ROMC supports ROM sizes with a range of 16 Kbyte to 4 Mbyte with an increment of 1 Kbyte. The 16 Kbyte lower limit was chosen because the minimum size of security code on an ARM platform is approximately 16 Kbyte of code, which is only accessible in supervisor mode. Note that it is the MMU that controls whether any region of memory is secure.

The exception vectors must be secured as well, and must be put in the same area as the security code. Since they must reside at address 0x0000_0000, the entire 16 Kbyte of ROM which can only be accessible in supervisor mode is located at the very beginning of the platform memory map.

If the user chooses not to use the security code, a memory size smaller than 16 Kbyte can be connected to the platform (minimum of 1 Kbyte). The MMU can be programmed to allow any kind of access into this memory. However, if the ROM size is less than 16 Kbyte, memory aliasing will occur for all invalid addresses greater than the memory size but within the 16 Kbyte of space.

For ROM sizes bigger than 16 Kbyte, the rest of its physical size resides at the address starting at 0x0040_4000 (4 M+16 Kbyte) going up to [0x0040_4000 + (mem. size - 16Kbyte)]. .

44.4 Functional Description

This section is divided up into the ROM Controller Functional Description and the ROMC functional description.

44.4.1 ROM Controller (ROMC) Functional Description

44.4.1.1 Functionality overview

The ROMC serves two main functions. First, as an interface between the AHB-Lite bus on an ARM platform and the ROM. Second, it drives and receives several signals for the BIST engine. In normal mode of operation, the ROMC monitors the AHB-Lite for memory access requests and performs the memory operation to the ROM.

The ROMC includes the option to wait state all accesses from either the ARM or non-ARM masters to ROM in the event that timing requirements will not allow single HCLK clock cycle reads. If a wait state is required, the static inputs `rom_wait_arm` or `rom_wait_alt_mstr` can be set to 1 and accesses will take two HCLK clock cycles. If wait states are not required, `rom_wait_arm` or `rom_wait_alt_mstr` can be set to 0 and accesses will take one HCLK clock cycle to complete.

44.4.2 ROMC Functional Description

44.4.2.1 ROMC Disabling

All the bits in the ROMC_ROMPATCHENL register are cleared on Reset, disabling all the address comparators. Once the comparators have been enabled, the ROMC functions of data fixing and opcode patching can be quickly disabled by setting the DIS bit in the ROMC_ROMPATCHCNTL register. This bit is used to enable secure operations in which patching functions need to be disabled. This bit is cleared on Reset.

44.4.2.2 ROMC Event Priority

The ROMC has a total of 16 address comparators. The first 8 (0 through 7) comparators can be programmed for the data fixing function (through the 8 data fix enable bits in the ROMC_ROMPATCHCNTL register) while the rest are for opcode patching by default. This allows for potential multiple matching events involving both data fixing and opcode patch types. In these cases the ROMC assigns the highest priority to a data fixing event.

For example, if the ROMC is set up to data fix a certain address with comparator 4 and also opcode patch the same address with comparator 7, it will let comparator 4 have higher priority in indicating a match, and data from ROMC_ROMPATCHD4 will be put on the rompatch_romc_hrdata bus as the override value.

If multiple address matches of the same type level occur concurrently, then the ROMC will choose the source number based on the one with the highest source number. For example, the ROMC is setup to data fix the same location with address comparators 4 and 7, then address comparator 7 will have higher priority in indicating a match, and the value from ROMC_ROMPATCHD7 will be put on the rompatch_romc_hrdata bus as the override value. The same priority applies for an opcode patch event, except the override data is in the form of an SWI instruction with the comment field set to the source number with the highest priority.

44.4.2.3 Data Fixing

The data fixing feature allows ROM data to be updated by direct replacement when it is being read. This data usually originates from data tables, but can include ARM instructions. To enable data fixing on a certain address, this address value is written in to one of the first eight (0 through 7) of ROMC_ROMPATCHAxx registers and the same numbered bit set in the ROMC_ROMPATCHENL and ROMC_ROMPATCHCNTL registers. The data to be used for replacement is placed in the corresponding ROMC_ROMPATCHDxx.

The ROMC looks for a read access to ROM (either code fetch or data load) by snooping the AHB interface for read transactions. The address is compared with the values stored in the ROMC_ROMPATCHAxx[22:2] registers. If a match occurs from one of the comparators, the ROMC places the value in the corresponding ROMC_ROMPATCHDxx register on the read data bus by overriding the read data coming from the actual ROM (see the mux in [Figure 44-1](#)). The value on the read data bus is maintained until hready is asserted to terminate the access. In data fixing, the entire word is replaced so if a byte or half-word access occurs on a "data fix" location, the entire data word is replaced. The word being replaced is word aligned. (The two LSBs of the matching ROMC_ROMPATCHAxx are ignored in the data fix operation.)

44.4.2.4 Opcode Patching

The opcode patch feature provides the ARM core a mechanism to fetch updated versions of code routines that were originally programmed in ROM. This patching mechanism makes use of the SWI (software interrupt instruction) and a table of function pointers residing in writable memory. The opcode being patched is replaced with a SWI instruction by the ROMC. Subsequent processing of the SWI reads from a function pointers table to obtain the address of the replacement code. Execution resumes with this code patch.

To enable opcode patching of a certain address, this address value is written into one of the ROMPATCHAxx registers and the corresponding bit set in the ROMPATCHENL to enable the associated comparator. The register's LSB (ROMC_ROMPATCHxx[0]) should be set if THUMB mode patching is in effect for this address. The ROMC identifies a ROM read access by snooping the AHB interface. The address is compared with the values stored in the ROMC_ROMPATCHAxx[22:2] registers. If a match occurs from one of the comparators, the ROMC generates the opcode of a software interrupt (SWI) instruction with the comment field containing the number of the matching address comparator. This opcode and comment is placed on the read data bus until hready is asserted by the ROM controller to terminate the read access.

The type of SWI generated, (that is, either ARM or THUMB), is determined by the LSB of the ROMC_ROMPATCHAxx register associated with the opcode patch. This bit is cleared for ARM mode (32 bits). The ROMC generates a 32-bit SWI (opcode field is 0xEF, occupying bits [31:24] of the word), with the least significant 5 bits of the 24-bit comment field (bits [23:0]) containing the number of the matching address comparator. The rest of the comment field is filled with zeros. This means that the ROMC will use 16 of the 16777216 possible software interrupts. The ROMC overrides the read data from the ROM.

If the LSB of the matching ROMC_ROMPATCHAxx register is set, the opcode patch is in THUMB mode (16 bits or half word). The ROMC generates a 16-bit SWI instruction (opcode field is 0xDF, occupying bits [15:8] of the half word) with the least significant 5 bits of the 8-bit comment field containing with the source number of the address comparator. The rest of the comments field is filled with zeros. This means that the ROMC will use 16 of the 256 possible software interrupts. The ROMC puts this 16 bit SWI instruction value on the proper half of the rompatch_romc_hrdata bus. The other half is zeroed out. Which half of the bus contains the SWI opcode and comment depends on the mode (Big Endian or Little Endian) and the bit 1 of the matching ROMC_ROMPATCHAxx register. In Little Endian mode, the lower half is bits {15:0} and the upper half is bits {31:16}. The order is reversed in Big Endian mode.

In Little Endian mode (bigend signal negated), if bit 1 of the matching ROMC_ROMPATCHAxx is cleared (lower half word selected) then the SWI instruction is put on the lower 16 bits of the read data bus and the upper 16 bits are zeroed out. Only the lower 16 bits of the read data bus is overwritten by the ROMC data. If ROMC_ROMPATCHAxx[1] is set (upper half word selected), the SWI instruction is put on the upper 16 bits of the read data bus and the lower 16 bits are zeroed out. Only the upper 16 bits of the read data bus is overwritten.

In Big Endian mode (bigend asserted), if bit 1 of the matching ROMC_ROMPATCHAxx is cleared (lower half word selected) then the SWI instruction is put on the upper 16 bits of the read data bus while the lower 16 bits are zeroed out. Only the upper 16 bits of the read data bus is overwritten. If ROMC_ROMPATCHAxx[1] is set (upper word selected), the SWI instruction is put on the lower 16 bits and the upper 16 bits are zeroed out. Only the lower 16 bits of the read data bus is overwritten.

The eventual execution of the SWI causes the ARM to save the CPSR in SPSR_SVC, the address of the next instruction after the SWI in R14_SVC, enter Supervisor mode, and fetch the SWI vector at 0x8, which then takes it to a handler for further processing as described in the next section.

44.4.2.4.1 Typical Software Response to Opcode Patch

When the SWI handler executes it needs to determine whether the SWI was generated by the ROMC. This is done by loading the SWI instruction and extracting its comment field. The state of the ARM core (ARM or THUMB) when the SWI was executed dictates whether to load the instruction word (ARM) or half word (THUMB). This state information can be determined by testing the T bit (bit 5) of the SPSR. If it's set, the execution was in THUMB mode.

By convention, if the comment field of the SWI is greater than 16, the software interrupt was initiated by software (i.e. an operating system call), and a branch is taken to the appropriate handler routine for further processing. If the comment field is less than 16, the SWI was generated by the ROMC performing a code patch operation. In this case, the software then reads from a table of function pointers, using the value in the SWI comment field as the index into the table. The value that is read is the address of the code patch. This value is loaded into the PC to begin the execution of the code patch. The following code segment illustrates a typical handling of the SWI.

```

stmfd      sp!, {r0-r1,lr}          @ push register onto SWI stack
mrs       r0, spsr                 @ get saved status register
tst       r0, #0x20                 @ check if call was in THUMB mode
ldrneh    r0, [lr,#-2]              @ yes: load opcode half-word and
bicne    r0, r0, #0xff00           @ yes: extract THUMB comment
ldreq     r0, [lr,#-4]              @ no: load opcode word and
biceq     r0, r0, #0xff000000       @ no: extract ARM comment
                                                @ now r0 has comment field

                                                @ handler
ldmfd     sp!, {r0-r1,pc}^         @ >= 16: pop registers from stack

```

44.4.2.5 External Boot Feature

Following a Reset event, the ARM issues an instruction fetch of the Reset Vector from address 0x0. This instruction, normally residing in ROM is usually a branch to a Reset handler or boot code which also normally resides in ROM. The ROMC external boot feature allows the bypassing of this code, using a different boot code residing perhaps in external memory.

This feature uses the data fix mechanism and works as follows: if the boot_int signal is negated when a Reset event occurred, the ROMC will perform a data fix of the Reset Vector at 0x0 with the following instruction (opcode 0xE59FF00C):

```

ldr       pc, [pc, #12]             @ read 0x0000_0014 for reset_vector

```

The value of PC when this instruction is executed is 8 so that a PC relative offset of 12 makes the source address 20 or 0x14. When this instruction executes, the ARM core reads from address 0x0000_0014, triggering a ROMC data fix operation which places the

value taken from the external boot address on the read data bus, with the two LSBs zeroed out. This value is returned to the ARM to be placed in the PC causing code fetch and execution to start from that address.

44.4.2.6 Alternate Masters and ROMC

The ROMC sits on the AHB bus of the internal ROM (ROMC). This means that the ROMC can modify values on the read data bus going to the master. Therefore, any master which reads an opcode patched or data patched location will read patched data.

44.5 ROMCP Memory Map/Register Definition

All registers are accessible through an IP Bus and can only be accessed in privileged mode. These registers can only be written with 32-bits stores and are clocked by hclk_reg.

ROMC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
21A_C0D4	ROMC Data Registers (ROMC_ROMPATCH7D)	32	R/W	0000_0000h	44.5.1/2870
21A_C0D8	ROMC Data Registers (ROMC_ROMPATCH6D)	32	R/W	0000_0000h	44.5.1/2870
21A_C0DC	ROMC Data Registers (ROMC_ROMPATCH5D)	32	R/W	0000_0000h	44.5.1/2870

44.5.1 ROMC Data Registers (ROMC_ROMPATCHnD)

The ROMC data registers (ROMC_ROMPATCH 7D through ROMC_ROMPATCH 0D) store the data to use for the 8 1-word data fix events. Each register is associated with an address comparator (7 through 0). When a data fixing event occurs, the value in the data register corresponding to the comparator that has the address match is put on the romc_hrdata[31:0] bus until romc_hready is asserted by the ROM controller to terminate the access. A MUX external to the ROMC will select this data over that of romc_hrdata[31:0] in returning read data to the ARM core. The selection is done with the control bus rompatch_romc_hrdata_ovr[1:0] with both bits asserted by the ROMC.

If more than one address comparators match, the highest-numbered one takes precedence, and the value in corresponding data register is used for the patching event.

Address: 21A_C000h base + D4h offset + (4d × i), where i=0d to 7d

ROMC_ROMPATCHnD field descriptions

Field	Description
DATAx	Data Fix Registers - Stores the data used for 1-word data fix operations. The values stored within these registers do not affect the writes to the memory system. They are selected over the read data from ROM when a data fix event occurs. If any part of the 1-word data fix is read, then the entire word is replaced. Therefore, a byte or half-word read will cause the ROMC to replace the entire word. The word is word address aligned.

44.5.2 ROMC Control Register (ROMC_ROMPATCHCNTL)

The ROMC control register (ROMC_ROMPATCHCNTL) contains the block disable bit and the data fix enable bits. The block disable bit provides a means to disable the ROMC data fix and opcode patching functions, even when the address comparators are enabled. The External Boot feature is not affected by this bit. The eight data fix enable bits (0 through 7), when set, assign the associated address comparators to data fix operations

NOTE

Bits 27 and 22 always read as 1s.

Address: 21A_C000h base + F4h offset = 21A_C0F4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R																
W	Reserved		DIS	Reserved

R	Reserved								DATAFIX							
W	Reserved								DATAFIX							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ROMC_ROMPATCHCNTL field descriptions

Field	Description
31–30 -	This field is reserved. Reserved
29 DIS	ROMC Disable -- This bit, when set, disables all ROMC operations. This bit is used to enable secure operations. 0 Does not affect any ROMC functions (default) 1 Disable all ROMC functions: data fixing, and opcode patching
28–8 -	This field is reserved. Reserved
DATAFIX	Data Fix Enable - Controls the use of the first 8 address comparators for 1-word data fix or for code patch routine. 0 Address comparator triggers a opcode patch 1 Address comparator triggers a data fix

44.5.3 ROMC Enable Register High (ROMC_ROMPATCHENH)

The ROMC enable register high (ROMC_ROMPATCHENH) and ROMC enable register low (ROMC_ROMPATCHENL) control whether or not the associated address comparator can trigger a opcode patch or data fix event. This implementation of the ROMC only has 16 comparators, therefore ROMC_ROMPATCHENH and the upper half of ROMC_ROMPATCHENL are read-only. ROMC_ROMPATCHENL[15:0] are associated with comparators 15 through 0. ROMC_ROMPATCHENLH[31:0] would have been associated with comparators 63 through 32.

Address: 21A_C000h base + F8h offset = 21A_C0F8h

ROMC_ROMPATCHENH field descriptions

Field	Description
-	This field is reserved. Reserved

44.5.4 ROMC Enable Register Low (ROMC_ROMPATCHENL)

The ROMC enable register high (ROMC_ROMPATCHENH) and ROMC enable register low (ROMC_ROMPATCHENL) control whether or not the associated address comparator can trigger a opcode patch or data fix event. This implementation of the ROMC only has 16 comparators, therefore ROMC_ROMPATCHENH and the upper half of ROMC_ROMPATCHENL are read-only. ROMC_ROMPATCHENL[15:0] are associated with comparators 15 through 0. ROMC_ROMPATCHENLH[31:0] would have been associated with comparators 63 through 32.

Address: 21A_C000h base + FCh offset = 21A_C0FCh

ROMC_ROMPATCHENL field descriptions

Field	Description
31–16 Reserved	This field is reserved.
ENABLE	<p>Enable Address Comparator - This bit enables the corresponding address comparator to trigger an event.</p> <p>0 Address comparator disabled</p> <p>1 Address comparator enabled, ROMC will trigger a opcode patch or data fix event upon matching of the associated address</p>

44.5.5 ROMC Address Registers (ROMC_ROMPATCHnA)

The ROMC address registers (ROMC_ROMPATCHA0 through ROMC_ROMPATCHA15) store the memory addresses where opcode patching begins and data fixing occurs. The address registers ROMC_ROMPATCHA0 through ROMC_ROMPATCHA15 are each 21 bits wide and dedicated to one 4 Mbyte memory space. Bits 21 through 2 are address bits, to be compared with romc_haddr[21:2] for a match; bit 1 is also an address bit used for half word selection. Bit 0 is the mode bit (set to 1 for THUMB mode). 1-word data fixing can only be used on the first 8 of the address comparators. ROMC_ROMPATCHA0 through ROMC_ROMPATCHA15 are associated each with address comparators 0 through 15.

Address: 21A_C000h base + 100h offset + (4d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								ADDRX

Table continues on the next page...

ROMC_ROMPATCHnA field descriptions (continued)

Field	Description
22–1 ADDRX	Address Comparator Registers - Indicates the memory address to be watched. All 16 registers can be used for code patch address comparison. Only the first 8 registers can be used for a 1-word data fix address comparison. Bit 1 is ignored if data fix. Only used in code patch
0 THUMBX	THUMB Comparator Select - Indicates that this address will trigger a THUMB opcode patch or an ARM opcode patch. If this watchpoint is selected to be a data fix, then this bit is ignored as all data fixes are 1-word data fixes. 0 ARM patch 1 THUMB patch (ignore if data fix)

44.5.6 ROMC Status Register (ROMC_ROMPATCHSR)

The ROMC status register (ROMC_ROMPATCHSR) indicates the current state of the ROMC and the source number of the most recent address comparator event.

Address: 21A_C000h base + 208h offset = 21A_C208h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved														SW	Reserv ed
W	Reserved														w1c

31–18 -	This field is reserved. Reserved
17 SW	ROMC AHB Multiple Address Comparator matches Indicator - Indicates that multiple address comparator matches occurred. Writing a 1 to this bit will clear this it. 0 no event or comparator collisions 1 a collision has occurred
16–6 -	This field is reserved. Reserved
SOURCE	ROMC Source Number - Binary encoding of the number of the address comparator which has an address match in the most recent patch event on ROMC AHB. If multiple matches occurred, the highest priority source number is used.

Table continues on the next page...

ROMC_ROMPATCHSR field descriptions (continued)

Field	Description
0	Address Comparator 0 matched
1	Address Comparator 1 matched
15	Address Comparator 15 matched

Chapter 45

Random Number Generator (RNGB)

45.1 Introduction

The purpose of the RNGB is to generate cryptographically strong random data.

It uses the True Random Number Generator (TRNG) and a Pseudo-Random Number Generator (PRNG) to achieve a true randomness and cryptographic strength. The RNGB generates random numbers for secret keys, per message secrets, random challenges, and other similar quantities used in the cryptographic algorithms.

This chapter describes the Random Number Generator (RNGB), including the programming model, functional description, and application information.

45.1.1 Block diagram

These figures show the RNGB's three main blocks: PRNG, TRNG, and XSEED generator.

Figure 45-1. RNG block diagram

45.1.2 Features

The RNG includes these distinctive features:

- National Institute of Standards and Technology (NIST)-approved pseudo-random number generator
 - <http://csrc.nist.gov>
- Supports the key generation algorithm defined in the Digital Signature Standard
 - <http://www.itl.nist.gov/fipspubs/fip186.htm>
- Integrated entropy sources capable of providing the PRNG with the entropy for its seed.

45.2 Modes of operation

Operational modes of the RNGB can be found here.

45.2.1 Self-test mode

In this mode, the RNGB performs a self test of the statistical counters and the PRNG algorithm to verify that the hardware is functioning properly. The self test takes ~29,000 cycles to complete. When the self test completes, an interrupt can be generated if there are no outstanding commands in the command register. This mode is entered by setting the RNG_CMD[ST] bit. When the self-test mode completes, the RNGB remains idle until the seed mode is requested or the RNGB transitions to seed mode if the automatic seeding is enabled.

45.2.2 Seed-generation mode

During the seed generation, the RNGB adds the entropy generated in the TRNG to the 256-bit XKEY register. The PRNG algorithm executes 20,000 entropy samples from the TRNG to create an initial seed for the random number generation. At the same time, the TRNG runs simple statistical tests on its output.

When the seed generation is complete, the TRNG reports the pass/fail result of the tests through RNG_ESR. If the new seed passes the statistical tests, the RNG_SR[SDN] is set, signalling that the RNG is ready to compute the secure pseudo-random data. The RNG then transitions to the random number generation mode.

45.2.3 Random number generation mode

When the seed-generation mode completes and the output FIFO is empty, the RNG enters this mode automatically. The random number generation mode quickly creates the computationally-random data that is derived by the initial seed produced in the seed-generation mode.

During the random number generation, a new 160-bit random number is generated whenever the five-word output FIFO is empty. When the output FIFO contains data, the RNGB automatically enters the sleep mode, waiting for the data to be read. When the data is read, the RNGB generates a new 160-bit word and goes back to sleep.

After generating 2^{20} words of random data, the RNGB lets the user know that it requires reseeding through RNG_SR and continues to generate random data until it is directed to reseed. However, if the auto-seeding is selected, the RNGB automatically completes the seeding whenever it is needed.

45.3 Memory map/register definition

The following table shows the address map for the RNGB module. The detailed register descriptions are explained in the following sections.

RNGB memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
228_4000	RNGB version ID register (RNG_VER)	32	R	1000_0280h	45.3.1/2880
228_4004	RNGB command register (RNG_CMD)	32	R/W	0000_0000h	45.3.2/2880
228_4008	RNGB control register (RNG_CR)	32	R/W	0000_0000h	45.3.3/2882
228_400C	RNGB status register (RNG_SR)	32	R	0000_500Dh	45.3.4/2884
228_4010	RNGB error status register (RNG_ESR)	32	R	0000_0000h	45.3.5/2886
228_4014	RNGB Output FIFO (RNG_OUT)	32	R	0000_0000h	45.3.6/2888

45.3.1 RNGB version ID register (RNG_VER)

The read-only RNG_VER register contains the current version of the RNGB. It consists of the RNG type and the major and minor revision numbers.

Address: 228_4000h base + 0h offset = 228_4000h

RNG_VER field descriptions

Field	Description
31–28 TYPE	Random number generator type 0000 RNGA 0001 RNGB (This is the type used in this module.) 0010 RNGC Else Reserved
27–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–8 MAJOR	Major version number This field is always set to 0x02.
MINOR	Minor version number Subject to change

45.3.2 RNGB command register (RNG_CMD)

The RNG_CMD controls the RNG's operating modes and interrupt status.

Address: 228_4000h base + 4h offset = 228_4004h

RNG_CMD field descriptions

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 SR	Software reset Perform a software reset of the RNGB. This bit is self-clearing. 0 Do not perform a software reset. 1 Software reset
5 CE	Clear the error. Clear the errors in the RNG_ESR register and the RNGB interrupt. This bit is self-clearing. 0 Do not clear the errors and the interrupt. 1 Clear the errors and the interrupt.
4 CI	Clear the interrupt. Clear the RNGB interrupt if an error is not present. This bit is self-clearing. 0 Do not clear the interrupt. 1 Clear the interrupt.
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 GS	Generate the seed. Initiates the seed generation process. The seed generation starts. <ul style="list-style-type: none"> When the RNG_SR[BUSY] is cleared. If set simultaneously with the ST, after the self test. When the seed generation process completes, this bit automatically clears and an interrupt can be generated if all requested operations are complete. 0 Not in the seed generation mode 1 Generate the seed mode.
0 ST	Self test Initiates a self test of the RNGB's internal logic. The self test starts. <ul style="list-style-type: none"> When RNG_SR[BUSY] is cleared. If set simultaneously with the GS, the self test takes the precedence and is completed first. When the self test completes, this bit automatically clears and an interrupt may be generated if all requested operations are complete. 0 Not in the self-test mode 1 Self-test mode

45.3.3 RNG control register (RNG_CR)

By using this register, the RNG can be programmed to provide a slightly different functionality based on its desired use.

Address: 228_4000h base + 8h offset = 228_4008h

RNG_CR field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 MASKERR	Mask the error interrupt. Masks the interrupts generated by errors in the RNGB. These errors can still be viewed in RNG_ESR. NOTE: Because the masked errors do not interrupt the operation of the RNGB and thus hide the potentially fatal errors or conditions that can result in corrupted results, it is strongly recommended to mask the errors while debugging. All errors are considered fatal, requiring the RNGB to be reset. Until the reset occurs, the RNGB does not service any random data. 0 No mask is applied. 1 The mask applied to the error interrupt
5 MASKDONE	Mask the interrupt done. Masks the interrupts generated upon the completion of the seed and self-test modes. The status of these jobs can be viewed by: <ul style="list-style-type: none"> Reading the RNG_SR and viewing the seed done and the self-test done bits (RNG_SR[SDN, STDN]). Viewing the RNG_CMD for the generate-seed or the self-test bits (RNG_CMD[GS,ST]) being set, indicating that the operation is still taking place.

Table continues on the next page...

RNG_CR field descriptions (continued)

Field	Description
	0 No mask is applied. 1 The mask is applied.
4 AR	Auto-reseed Setting this bit enables the RNGB to automatically generate a new seed whenever it is needed. This enables the software to never use the RNG_CMD[GS], although it is still possible. A new seed is needed whenever the RNG_SR[RS] is set. 0 Do not enable the automatic reseeding. 1 Enable the automatic reseeding.
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
FUFMOD	FIFO underflow response mode Controls the RNGB's response to a FIFO underflow condition. 00 Return all zeros and set the RNG_ESR[FUFE]. 01 Return all zeros and set the RNG_ESR[FUFE]. 10 Generate the bus transfer error 11 Generate the interrupt and return all zeros (overrides the RNG_CR[MASKERR]).

45.3.4 RNGB status register (RNG_SR)

The RNGBSR is a read-only register which reflects the internal status of the RNGB.

Address: 228_4000h base + Ch offset = 228_400Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	STATPF								ST_PF			0				ERR
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	FIFO_SIZE				FIFO_LVL				0	NSDN	SDN	STDN	RS	SLP	BUSY	1
W																
Reset	0	1	0	1	0	0	0	0	0	0	0	0	1	1	0	1

RNG_SR field descriptions

Field	Description
31–24 STATPF	<p>Statistics test pass failed.</p> <p>Indicates the pass or fail status of the various statistics tests on the last seed generated.</p> <ul style="list-style-type: none"> • Bit 31 - Long run test (>34) • Bit 30 - Length 6+ run test • Bit 29 - Length 5 run test • Bit 28 - Length 4 run test • Bit 27 - Length 3 run test • Bit 26 - Length 2 run test • Bit 25 - Length 1 run test • Bit 24 - Monobit test <p>0 Pass 1 Fail</p>
23–21 ST_PF	<p>Self-test pass fail</p> <p>Indicates the pass or fail status of the TRNG, PRNG, and RESEED self tests.</p> <ul style="list-style-type: none"> • Bit 23 - TRNG self test pass/fail

Table continues on the next page...

RNG_SR field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> • Bit 22 - PRNG self test pass/fail • Bit 21 - RESEED self test pass/fail 0 Pass 1 Fail
20–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 ERR	Error Indicates that an error was detected in the RNGB. Read the RNG_ESR register for details. 0 No error 1 Error detected
15–12 FIFO_SIZE	FIFO size Size of the FIFO, and the maximum possible FIFO level. The bits must be interpreted as an integer. This value is set to 5 on the default version of the RNGB.
11–8 FIFO_LVL	FIFO level Indicates the number of random words currently in the output FIFO. The bits must be interpreted as an integer.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 NSDN	New seed done Indicates that a new seed is ready for use during the next seed-generation process.
5 SDN	Seed done Indicates that the RNG generated the first seed. 0 The seed-generation process is not complete. 1 Completed the seed generation since the last reset
4 STDN	Self test done Indicates that the self test is complete. This bit is cleared by the hardware reset or a new self test is initiated by setting the RNG_CMD[ST]. 0 Self test not completed 1 Completed a self test since the last reset
3 RS	Reseed needed Indicates that the RNGB needs to be reseeded. This is done by setting the RNG_CMD[GS], or automatically if the RNG_CR[AR] is set. 0 The RNGB does not need to be reseeded. 1 The RNGB needs to be reseeded.
2 SLP	Sleep Indicates whether the RNGB is in the sleep mode. When set, the RNGB is in the sleep mode and all internal clocks are disabled. While in this mode, access to the FIFO is allowed. Once the FIFO is empty, the RNGB fills the FIFO and then enters sleep mode again.

Table continues on the next page...

RNG_SR field descriptions (continued)

Field	Description
	0 The RNGB is not in the sleep mode. 1 The RNGB is in the sleep mode.
1 BUSY	Busy. Reflects the current state of the RNGB. If the RNGB is currently seeding, generating the next seed, creating a new random number, or performing a self test, this bit is set. 0 Not busy 1 Busy
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.

45.3.5 RNGB error status register (RNG_ESR)

Address: 228_4000h base + 10h offset = 228_4010h

RNG_ESR field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

RNG_ESR field descriptions (continued)

Field	Description
4 FUFE	<p>FIFO underflow error</p> <p>Indicates that the RNGB has experienced a FIFO underflow condition, resulting in the last random data read being unreliable. This bit can be masked by the RNG_CR[FUFMOD] and is cleared by a hardware or software reset or by writing 1 to the RNG_CMD[CE].</p> <p>0 FIFO underflow did not occur. 1 FIFO underflow occurred.</p>
3 SATE	<p>Statistical test error</p> <p>Indicates whether the RNGB failed the statistical tests for the last generated seed. This bit is sticky and is cleared by a hardware or software reset or by writing 1 to the RNG_CMD[CE].</p> <p>0 The RNGB did not fail the statistical tests. 1 The RNGB failed the statistical tests during the initialization.</p>
2 STE	<p>Self-test error</p> <p>Indicates that the RNGB failed the most recent self test. This bit is sticky and can only be reset by a hardware reset or by writing 1 to the RNG_CMD[CE].</p> <p>0 The RNGB did not fail the self test. 1 The RNGB failed the self test.</p>
1 OSCE	<p>Oscillator error</p> <p>Indicates that the oscillator in the RNG can be broken. This bit is sticky and can only be cleared by a software or hardware reset.</p> <p>0 The RNG oscillator is working properly. 1 A problem with the RNG oscillator was detected.</p>
0 LFE	<p>Linear feedback shift register (LFSR) error</p> <p>When this bit is set, the interrupt generated was caused by a failure of one of the LFSRs in one of the RNGB's three entropy sources. 45.3.6 RNG Output FIFO (RNG_OUT)

The RNGOUT provides a temporary storage for the random data generated by the RNG. This enables the user to read multiple random longwords back-to-back. A read of this address when the FIFO is not empty returns 32 bits of random data. If the FIFO is read when empty, a FIFO underrun response is returned according to the RNG_CR[FUFMOD]. For optimal system performance, poll the RNG_SR[FIFO_LVL] to ensure that random values are present before reading the FIFO.

Address: 228_4000h base + 14h offset = 228_4014h

RNG_OUT field descriptions

Field	Description
RANDOUT	Random output

45.4 Functional description

The RNG performs two functional operations: the seed generation and the random number generation.

These operations (described in [Modes of operation](#)) are performed in conjunction with the major functional blocks in the RNG described below.

45.4.1 Pseudo-Random Number Generator (PRNG)

The PRNG implements the NIST-approved PRNG described in the *Digital Signature Standard*. The 160-bit output of the SHA-1 block are the next five words of random data. The PRNG is designed to generate 2²⁰ words of random data before requiring reseeding, using the TRNG only during the seeding/initialization process. The initial seed takes approximately two million clock cycles. After this, the RNG can generate five 32-bit words every 112 clock cycles. The reseeding takes place transparently using the

simultaneous reseed LFSRs. The entropy stored in this 128-bit LFSR and the 128-bit shift register is added directly into the XKEY structure via the RNGB XSEED generator whenever the reseeding is required.

45.4.2 True Random Number Generator (TRNG)

The TRNG comprises of two entropy sources, with each providing a single bit of output. Concatenated together, these two output bits are expected to provide one bit of entropy every 100 clock cycles. In addition to generating the entropy, the TRNG also performs several statistical tests on its output. The pass/fail status of these tests is reflected in the RNG_ESR.

45.4.3 Resets

There are two ways to reset the RNGB: the power-on/hardware reset and the software reset. The software reset is functionally equivalent to the power-on/hardware reset. The power-on/hardware reset is asynchronous. The software reset is performed by setting the RNG_CMD[SR] bit. The resets are summarized in this table:

Table 45-1. Reset summary

Reset	Source	Characteristics	Internal resets	Effect on the external signal
Hardware	ipg_hard_async_reset_b	Active-low, asynchronous, minimum 1-cycle	Resets all interface registers and puts the RNGB into the IDLE state	—
Software	RNG_CMD[SR]	Active-high	Resets all interface registers and puts the RNGB into the IDLE state	—

45.4.3.1 Power-on/hardware reset

Asserting the ipg_hard_async_reset_b signal sets all interface registers to their default state and puts the state machine into the IDLE state.

45.4.3.2 Software reset

The software reset is functionally equivalent to the hardware reset, but enables the RNGB to be fully reset by writing to the SW_RST bit (bit-6) into the RNGB command register. This bit is self-resetting. The software reset can be performed at any time.

45.4.4 RNG interrupts

There is a single RNG interrupt, generated to the processor's interrupt controller. The source of the interrupt is determined by reading the RNG status register. If an error is the cause of the interrupt, further information is available by reading the RNG error status register. The interrupts can be masked by the RNG_CR[MASKDONE or MASKERR] bits.

It is strongly recommended to mask the error interrupt only while debugging because masking the error interrupt can hide the potentially fatal errors or conditions that can result in corrupted results. All errors are considered fatal, requiring the RNG to be reset. The RNG does not service any random data until a reset occurs.

The available interrupt sources are described in this table:

Table 45-2. RNG interrupt sources

Sources	Status bit field	RNG_CR mask bit field	Description
Seed generation done	RNG_SR[SDN]	MASKDONE	The first seed was generated
Self test done	RNG_SR[STDN]	MASKDONE	Self test finished
Error	RNG_SR[ERR]	MASKERR	Error detected—see RNG_ESR for details
Linear Feedback Shift Register (LFSR)	RNG_ESR[LSFRE]	MASKERR	Fault in one of the TRNG's LFSRs
Oscillator	RNG_ESR[OSCE]	MASKERR	TRNG ring oscillator may be malfunctioning
Self test	RNG_ESR[STE]	MASKERR	Self test failed
Statistical test	RNG_ESR[SATE]	MASKERR	Statistics test for the last seed generation failed
FIFO underflow	RNG_ESR[FUFE]	MASKERR	FIFO read while empty

45.5 Initialization/application information

The information located here describes the module initialization.

45.5.1 Manual seeding

The intended general operation of the RNGB is as follows:

1. Reset/initialize.
2. Write to the RNG_CR to setup the RNGB for the desired functionality.
3. Write to the RNG_CMD to run the self test or seed generation.
4. Wait for an interrupt to indicate the completion of the requested operation(s).
5. Repeat steps 3–4 if the seed generation is not complete.
6. Poll the RNG_SR for the FIFO level.
7. Read the available random data from the output FIFO.
8. Repeat steps 6 and 7 as needed, until 2^{20} words are generated.
9. Write to the RNG_CMD to run the seed mode.
10. Repeat steps 4–9.

45.5.2 Automatic seeding

The intended general operation of the RNGB with the automatic seeding enabled is as follows:

1. Reset/initialize.
2. Write to the RNG_CR to setup the RNGB for automatic seeding and the desired functionality.
3. Wait for an interrupt to indicate the completion of the first seed.
4. Poll the RNG_SR for the FIFO level.
5. Read the available random data from the output FIFO.
6. Repeat steps 4 and 5 as needed. The automatic seeding occurs when necessary and is transparent to the operation.

Chapter 46

Synchronous Audio Interface (SAI)

46.1 Overview

The synchronous audio interface (SAI) supports full-duplex serial interfaces with frame synchronization such as I²S, AC97, TDM, and codec/DSP interfaces.

46.1.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 1 data line
- Receiver with independent bit clock and frame sync supporting 1 data line
- Maximum Frame Size of 32 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 32 × 32-bit FIFO for each transmit and receive channel
- Supports graceful restart after FIFO error

46.1.2 Block diagram

The following block diagram also shows the module clocks.

Figure 46-1. I²S/SAI block diagram

46.1.3 Modes of operation

The module operates in these power modes: Run mode, stop modes, and Debug mode.

46.1.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

46.1.3.2 Stop modes

In Stop mode, the transmitter is disabled after completing the current transmit frame, and, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented—not acknowledged—while waiting for the transmitter and receiver to be disabled at the end of the current frame.

46.1.3.3 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

46.2 External Signals

The following table describes the external signals of SAI:

Table 46-1. SAI External Signals

Signal	Description	Pad	Mode	Direction
SAI1_MCLK	Audio Master Clock. The master clock is an input when externally generated and an output when internally generated.	CSI_DATA01	ALT6	IO
		LCD_DATA00	ALT8	
SAI1_RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	CSI_DATA03	ALT6	IO
SAI1_RX_DATA	Receive Data. The receive data is sampled synchronously by the bit clock.	CSI_DATA06	ALT6	I
		LCD_DATA03	ALT8	
SAI1_RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	CSI_DATA02	ALT6	IO
SAI1_TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	CSI_DATA05	ALT6	IO
		LCD_DATA02	ALT8	
SAI1_TX_DATA	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	CSI_DATA07	ALT6	O
		LCD_DATA04	ALT8	
SAI1_TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	CSI_DATA04	ALT6	IO
		LCD_DATA01	ALT8

46.3 Functional description

This section provides a complete functional description of the block.

46.3.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

46.3.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

46.3.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

46.3.1.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

NOTE

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

46.3.2 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

46.3.2.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

46.3.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

46.3.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other.

46.3.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

46.3.4 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 32 words per frame
- Word length to support 8 to 32 bits per word
 - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

46.3.5 Data FIFO

Each transmit and receive channel includes a FIFO of size 32×32 -bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

46.3.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in [Figure 46-2](#) for LSB First configurations and [Figure 46-3](#) for MSB First configurations.

Figure 46-2. SAI first bit shifted, LSB first

Figure 46-3. SAI first bit shifted, MSB first

46.3.5.2 FIFO pointers

When writing to a TDR, the WFP of the corresponding TFR increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the TDR and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data and 16-bit writes should only be used when transmitting up to 16-bit data.

Writes to a TDR are ignored if the corresponding bit of TCR3[TCE] is clear or if the FIFO is full. If the Transmit FIFO is empty, the TDR must be written at least three bit clocks before the start of the next unmasked word to avoid a FIFO underrun.

When reading an RDR, the RFP of the corresponding RFR increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data and 16-bit reads should only be used when receiving up to 16-bit data.

Reads from an RDR are ignored if the corresponding bit of RCR3[RCE] is clear or if the FIFO is empty. If the Receive FIFO is full, the RDR must be read at least three bit clocks before the end of an unmasked word to avoid a FIFO overrun.

46.3.6 Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

46.3.7 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags.

46.3.7.1 FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

46.3.7.2 FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

46.3.7.3 FIFO error flag

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels repeat the last valid word read from the transmit FIFO until TCSR[FEF] is cleared and the next transmit frame starts. All enabled transmit FIFOs must be reset and initialized with new data before TCSR[FEF] is cleared.

RCSR[FEF] is set when the any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

The FIFO error flag can generate only an interrupt.

46.3.7.4 Sync error flag

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

46.3.7.5 Word start flag

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

46.4 Memory map and register definition

A read or write access to an address from offset and above will result in a bus error.

I2S memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

I2Sx_TCSR field descriptions

Field	Description
31 TE	<p>Transmitter Enable</p> <p>Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame.</p> <p>0 Transmitter is disabled. 1 Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.</p>
30 STOPE	<p>Stop Enable</p> <p>Configures transmitter operation in Stop mode. This field is ignored and the transmitter is disabled in all stop modes.</p> <p>0 Transmitter disabled in Stop mode. 1 Transmitter enabled in Stop mode.</p>
29 DBGE	<p>Debug Enable</p>

Table continues on the next page...

I2Sx_TCSR field descriptions (continued)

Field	Description
	Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode. 0 Transmitter is disabled in Debug mode, after completing the current frame. 1 Transmitter is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame. 0 Transmit bit clock is disabled. 1 Transmit bit clock is enabled.
27–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 FR	FIFO Reset Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set. 0 No effect. 1 FIFO reset.
24 SR	Software Reset When set, resets the internal transmitter logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers. 0 No effect. 1 Software reset.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0 Start of word not detected. 1 Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0 Sync error not detected. 1 Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag. 0 Transmit underrun not detected. 1 Transmit underrun detected.

Table continues on the next page...

I2Sx_TCSR field descriptions (continued)

Field	Description
17 FWF	FIFO Warning Flag Indicates that an enabled transmit FIFO is empty. 0 No enabled transmit FIFO is empty. 1 Enabled transmit FIFO is empty.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark. 0 Transmit FIFO watermark has not been reached. 1 Transmit FIFO watermark has been reached.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0 Disables interrupt. 1 Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0 Disables interrupt. 1 Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FWDE	FIFO Warning DMA Enable

Table continues on the next page...

I2Sx_TCSR field descriptions (continued)

Field	Description
	Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.

46.4.2 SAI Transmit Configuration 1 Register (I2Sx_TCR1)

Address: Base address + 4h offset

I2Sx_TCR1 field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TFW	Transmit FIFO Watermark Configures the watermark level for all enabled transmit channels.

46.4.3 SAI Transmit Configuration 2 Register (I2Sx_TCR2)

This register must not be altered when TCSR[TE] is set.

Address: Base address + 8h offset

I2Sx_TCR2 field descriptions

Field	Description
31–30 SYNC	<p>Synchronous Mode</p> <p>Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver must be configured for asynchronous operation.</p> <p>00 Asynchronous mode. 01 Synchronous with receiver.</p>
29 BCS	<p>Bit Clock Swap</p> <p>This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (SAI_RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (SAI_TX_SYNC).</p> <p>When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (SAI_TX_BCLK) but use the receiver frame sync (SAI_RX_SYNC).</p> <p>0 Use the normal bit clock source. 1 Swap the bit clock source.</p>
28 BCI	<p>Bit Clock Input</p> <p>When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time.</p> <p>The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock .</p> <p>0 No effect. 1 Internal logic is clocked as if bit clock was externally generated.</p>
27–26 MSEL	<p>MCLK Select</p> <p>Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.</p> <p>NOTE: Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option.</p> <p>00 Master Clock (MCLK) 1 option selected. 01 Master Clock (MCLK) 1 option selected. 10 Master Clock (MCLK) 2 option selected. 11 Master Clock (MCLK) 3 option selected.</p>
25 BCP	<p>Bit Clock Polarity</p> <p>Configures the polarity of the bit clock.</p> <p>0 Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1 Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.</p>
24 BCD	<p>Bit Clock Direction</p>

Table continues on the next page...

I2Sx_TCR2 field descriptions (continued)

Field	Description
	Configures the direction of the bit clock. 0 Bit clock is generated externally in Slave mode. 1 Bit clock is generated internally in Master mode.
23–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is $(DIV + 1) * 2$.

46.4.4 SAI Transmit Configuration 3 Register (I2Sx_TCR3)

This register must not be altered when TCSR[TE] is set.

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	0								0								TCE
W	[Shaded]

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Sx_TCR3 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TCE	Transmit Channel Enable Enables the corresponding data channel for transmit operation. A channel must be enabled before its FIFO is accessed. 0 Transmit data channel N is disabled. 1 Transmit data channel N is enabled.
15–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
WDFL	Word Flag Configuration

Table continues on the next page...

I2Sx_TCR3 field descriptions (continued)

Field	Description
	Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set.

46.4.5 SAI Transmit Configuration 4 Register (I2Sx_TCR4)

This register must not be altered when TCSR[TE] is set.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R		0		0		0		0		0		FRSZ

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Sx_TCR4 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 FRSZ	Frame size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

I2Sx_TCR4 field descriptions (continued)

Field	Description
4 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0 LSB is transmitted first. 1 MSB is transmitted first.
3 FSE	Frame Sync Early 0 Frame sync asserts with the first bit of the frame. 1 Frame sync asserts one bit before the first bit of the frame.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0 Frame sync is active high. 1 Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0 Frame sync is generated externally in Slave mode. 1 Frame sync is generated internally in Master mode.

46.4.6 SAI Transmit Configuration 5 Register (I2Sx_TCR5)

This register must not be altered when TCSR[TE] is set.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																0															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Sx_TCR5 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

I2Sx_TCR5 field descriptions (continued)

Field	Description
20–16 WOW	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 FBT	First Bit Shifted Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB First, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB First, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.4.7 SAI Transmit Data Register (I2Sx_TDRn)

Address: Base address + 20h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																															
W	TDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Sx_TDRn field descriptions

Field	Description
TDR	Transmit Data Register The corresponding TCR3[TCE] bit must be set before accessing the channel's transmit data register. Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored.

46.4.8 SAI Transmit FIFO Register (I2Sx_TFRn)

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

Address: Base address + 40h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0						WFP								
W	[Reserved]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								RFP							
W	[Reserved]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Sx_TFRn field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 WFP	Write FIFO Pointer FIFO write pointer for transmit data channel.
15–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RFP	Read FIFO Pointer FIFO read pointer for transmit data channel.

46.4.9 SAI Transmit Mask Register (I2Sx_TMR)

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

Address: Base address + 60h offset

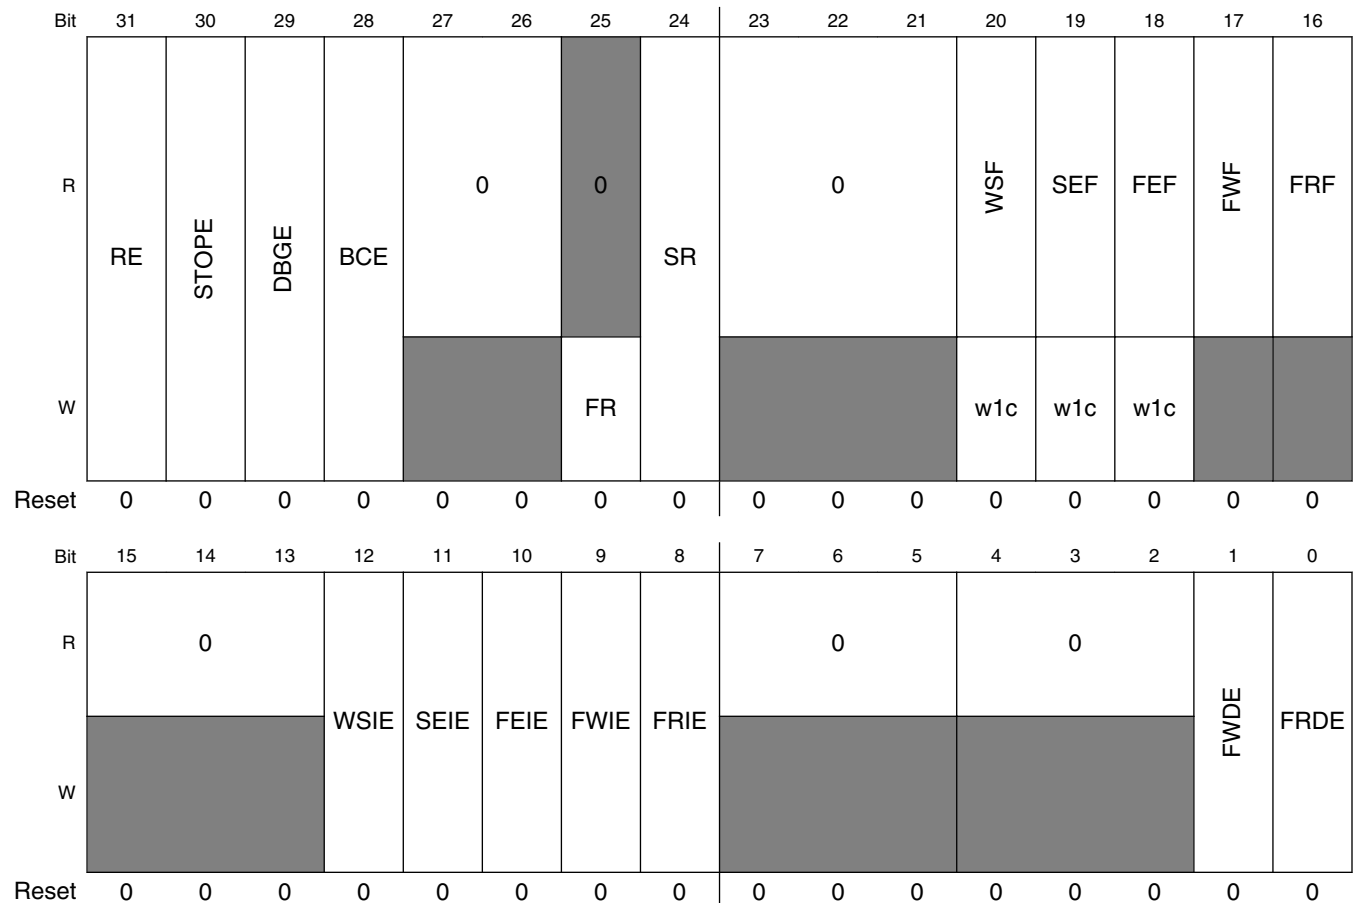

I2Sx_TMR field descriptions

Field	Description
TWM	<p>Transmit Word Mask</p> <p>Configures whether the transmit word is masked (transmit data pin tristated and transmit data not read from FIFO) for the corresponding word in the frame.</p> <p>0 Word N is enabled. 1 Word N is masked. The transmit data pins are tri-stated when masked.</p>

46.4.10 SAI Receive Control Register (I2Sx_RCSR)

Address: Base address + 80h offset

I2Sx_RCSR field descriptions

Field	Description
31 RE	<p>Receiver Enable</p> <p>Enables/disables the receiver. When software clears this field, the receiver remains enabled, and this bit remains set, until the end of the current frame.</p> <p>0 Receiver is disabled. 1 Receiver is enabled, or receiver has been disabled and has not yet reached end of frame.</p>
30 STOPE	<p>Stop Enable</p> <p>Configures receiver operation in Stop mode. This bit is ignored and the receiver is disabled in all stop modes.</p> <p>0 Receiver disabled in Stop mode. 1 Receiver enabled in Stop mode.</p>
29 DBGE	<p>Debug Enable</p> <p>Enables/disables receiver operation in Debug mode. The receive bit clock is not affected by Debug mode.</p> <p>0 Receiver is disabled in Debug mode, after completing the current frame. 1 Receiver is enabled in Debug mode.</p>
28 BCE	<p>Bit Clock Enable</p> <p>Enables the receive bit clock, separately from RE. This field is automatically set whenever RE is set. When software clears this field, the receive bit clock remains enabled, and this field remains set, until the end of the current frame.</p> <p>0 Receive bit clock is disabled. 1 Receive bit clock is enabled.</p>
27–26 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
25 FR	<p>FIFO Reset</p> <p>Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the receiver is disabled or the FIFO error flag is set.</p> <p>0 No effect. 1 FIFO reset.</p>
24 SR	<p>Software Reset</p> <p>Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers.</p> <p>0 No effect. 1 Software reset.</p>
23–21 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
20 WSF	<p>Word Start Flag</p> <p>Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag.</p>

Table continues on the next page...

I2Sx_RCSR field descriptions (continued)

Field	Description
	0 Start of word not detected. 1 Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0 Sync error not detected. 1 Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled receive FIFO has overflowed. Write a logic 1 to this field to clear this flag. 0 Receive overflow not detected. 1 Receive overflow detected.
17 FWF	FIFO Warning Flag Indicates that an enabled receive FIFO is full. 0 No enabled receive FIFO is full. 1 Enabled receive FIFO is full.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark. 0 Receive FIFO watermark not reached. 1 Receive FIFO watermark has been reached.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0 Disables interrupt. 1 Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0 Disables interrupt. 1 Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts.

Table continues on the next page...

I2Sx_RCSR field descriptions (continued)

Field	Description
	0 Disables the interrupt. 1 Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
7-5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4-2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.

46.4.11 SAI Receive Configuration 1 Register (I2Sx_RCR1)

Address: Base address + 84h offset

I2Sx_RCR1 field descriptions

Field	Description
31-5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RFW	Receive FIFO Watermark Configures the watermark level for all enabled receiver channels.

46.4.12 SAI Receive Configuration 2 Register (I2Sx_RCR2)

This register must not be altered when RCSR[RE] is set.

Address: Base address + 88h offset

I2Sx_RCR4 field descriptions (continued)

Field	Description
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 FRSZ	Frame Size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 MF	MSB First Configures whether the LSB or the MSB is received first. 0 LSB is received first. 1 MSB is received first.
3 FSE	Frame Sync Early 0 Frame sync asserts with the first bit of the frame. 1 Frame sync asserts one bit before the first bit of the frame.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0 Frame sync is active high. 1 Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0 Frame Sync is generated externally in Slave mode. 1 Frame Sync is generated internally in Master mode.

46.4.15 SAI Receive Configuration 5 Register (I2Sx_RCR5)

This register must not be altered when RCSR[RE] is set.

Address: Base address + 94h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

I2Sx_RCR5 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 WOW	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 FBT	First Bit Shifted Configures the bit index for the first bit received for each word in the frame. If configured for MSB First, the index of the next bit received is one less than the current bit received. If configured for LSB First, the index of the next bit received is one more than the current bit received. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

46.4.16 SAI Receive Data Register (I2Sx_RDRn)

Reading this register introduces one additional peripheral clock wait state on each read.

Address: Base address + A0h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RFP	<p>Read FIFO Pointer</p> <p>FIFO read pointer for receive data channel.</p>

46.4.18 SAI Receive Mask Register (I2Sx_RMR)

This register is double-buffered and updates:

1. When RCSR[RE] is first set
2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

Address: Base address + E0h offset

I2Sx_RMR field descriptions

Field	Description
RWM	<p>Receive Word Mask</p> <p>Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame.</p> <p>0 Word N is enabled. 1 Word N is masked.</p>

Chapter 47

Smart Direct Memory Access Controller (SDMA)

47.1 Overview

The Smart Direct Memory Access (SDMA) controller offers highly-competitive DMA features combined with software-based virtual-DMA flexibility. It enables data transfers between peripheral I/O devices and internal/external memories.

The SDMA controller helps maximize system performance by off-loading the ARM core in dynamic data routing.

47.1.1 Block Diagram

The figure below shows a block diagram of the SDMA controller. It includes the custom RISC core along with its RAM, ROM, DMA units, and the scheduler.

Figure 47-1. SDMA Block Diagram

The SDMA core executes short routines that perform DMA transfers; these routines are called *scripts*. The SDMA core interfaces to its own memory via the SDMA system bus. The SDMA system bus supports a 32-bit data path and a 16-bit address bus. The system bus datapath is used for both 16-bit instruction (program) memory access and 32-bit data access. DMA units interface to the core via the Functional Unit Bus and use dedicated registers to perform DMA transfers.

The SDMA memory contains a ROM and a RAM. The ROM contains startup scripts (for example, boot code) and other common utilities, which are referenced by the scripts that reside in the RAM. The internal RAM is divided into a context area and a script area (more details about this mapping are available in [Instruction Memory Map](#) and [Data Memory Map](#)).

Every transfer channel requires one context area to keep the contents of all the core and unit registers while inactive. Channel scripts are downloaded into the internal RAM by the SDMA using a dedicated channel that is started during the boot sequence. Downloads are invoked using commands and pointers provided by the ARM platform. Every channel contains a corresponding channel script located in RAM and/or ROM that can be reconfigured independently as-needed. Channel scripts can be stored in an external memory and downloaded when needed. The SDMA can be configured with any mixture of scripts to enable an endless combination of supported services.

The scheduler monitors and detects DMA requests, mapping them to channels, and mapping individual channels to a pre-configured priority. At any given point, the scheduler presents the highest priority channel that requires service to the SDMA core. A special SDMA core instruction is used to "conditionally yield" the current channel being executed to an eligible channel that requires service. If (and only if) there is an eligible channel pending, will the current channel execution be preempted.

There are two yield instructions that differently determine the eligible channels: In the first version, eligible channels are pending channels with a strictly higher priority than the current channel priority. In the second version (yieldge), eligible channels are pending channels with a priority that is greater or equal to the current channel priority. The scheduler detects devices that need service through its 48 DMA request inputs. After a request is detected, the scheduler determines the channel(s) that is (are) triggered by this request and marks it (them) as pending in the "Channel Pending (EP)" register. The priorities of all the pending channels are continuously evaluated in order to update the highest pending priority. The channel pending flag is cleared by the channel script when the transfer has completed.

The ARM platform control block contains the control registers used to configure the 32 individual channels. There are 48 Channel Enable registers, and every register maps one DMA request to any desired combination of channels. The 32 Priority registers are used to assign a programmable 1-of-7 level priority to every possible channel. This block also contains all other control registers that the ARM platform can access.

The 48 DMA requests that are connected to the scheduler come from a variety of sources. The "receive register full" and "transmit register empty" signals found in the UART and USB ports are typical examples of DMA requests that can be connected to the SDMA. These requests can be used to trigger a specific SDMA channel, or several channels.

There is an OnCE compatible debug port for product development. The OnCE includes support for setting breakpoints, single-step and trace, and register dump capability. In addition, all memory locations are accessible from the debug port.

47.1.2 Features

The following are the SDMA features:

- Multi-channel DMA supporting up to 32 time-division multiplexed DMA channels
- Hardware or software driven triggers for each channel
- 48 hardware driven triggers that can be mapped to any channel.
- Memory accesses including linear addressing, FIFO addressing and 2D addressing
- Fast context-switching with two-level, priority-based preemptive multi-tasking
- 16-bit instruction-set micro-RISC engine (the SDMA core)
- Two DMA units with some or all the following features:
 - Auto-flush and prefetch capability
 - Flexible address management (increment, decrement, and no address changes on source and destination address)
 - Misaligned data-transfer support
 - Uni-directional and bi-directional flows (copy mode)
 - Up to eight-word buffers for configurable burst transfers
- Support of byte-swapping
- An available API and library of scripts
- Little-Endian and Big-Endian modes
- Hardware handshakes for low-power entry sequence
- Security support to lock contents of the SDMA script RAM.
- 4-Kbyte ROM containing startup scripts (for example, boot code) and other common utilities that can be referenced by RAM-located scripts
- 8-Kbyte RAM area is divided into a processor context area and a code space area used to store channel scripts that are downloaded from the system memory
- Debug support, including a OnCE port, real-time monitors, and embedded cross-trigger events
- Supported clock frequencies in process:
 - Configurable clock options for the SDMA core and the ARM platform DMA units
 - 1:2 ratio with maximum of SDMA core running at ARM platform Peripheral Bus speed and DMA running at max DMA frequency.
 - 1:1 ratio when both SDMA core and ARM platform DMA clocks are set to the ARM platform Peripheral Bus speed.
- Peripheral bus interface for configuration register programming by the ARM platform
- The SDMA RISC engine (arithmetic and logic operations), which is referred to as the "SDMA core."
- An internal peripheral bus connected to the Shared Peripherals Bus Interface (SPBA) that enables access to up to 14 shared peripherals. SDMA supports 32-bit accesses to word peripherals and 16-bit accesses to half-word peripherals.

- The peripheral DMA unit that is hooked-up to the ARM platform Crossbar Switch to service ARM peripherals
- The burst DMA unit is able to perform burst accesses to the external memory
- All the DMA units are 32-bit AHB masters. They are connected to different buses, thus allowing concurrent accesses.

47.2 External Signals

The table found here describes the external signals of SDMA.

Table 47-1. SDMA External Signals

Signal	Description	Pad	Mode	Direction
SDMA_EVENT0	Event0 signal	GPIO1_IO02	ALT6	I
		JTAG_MOD	ALT6	
		SD1_CMD	ALT6	
SDMA_EVENT1	Event1 signal	JTAG_TMS	ALT6	I
		NAND_DQS	ALT6	

47.3 Clocks

The following table describes the clock sources for SDMA. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information. For functional information regarding module clocks, see [SDMA Clocks and Low Power Modes](#).

Table 47-2. SDMA Clocks

Clock name	Clock Root	Description
events_sync_clk (clk)	ahb_clk_root	ARM peripheral / events clock
ips_hostctrl_clk	ipg_clk_root	Host control clock
ap_ahb_clk	ahb_clk_root	ARM platform bus clock
core_clk	ipg_clk_root	Module / Core clock
tck	-	JTAG access clock

47.4 Functional Description

The figure below shows the SDMA topology, and is composed of the following components:

Functional Description

- SDMA Core ([SDMA Core](#))
- SDMA Scheduler ([Scheduler](#))
- Functional Units:
 - Burst DMA ([Burst DMA Unit](#))
 - Peripheral DMA ([Peripheral DMA Unit](#))
- ARM platform Control for ARM control register access.
- Internal RAM and ROM Memory ([SDMA Programming Model](#))
- OnCE debug Port ([The OnCE Controller](#))

The functional unit bus provides access by the SDMA core to the DMA units. The system bus provides access to SDMA internal memory and also supports up to 14 peripherals.

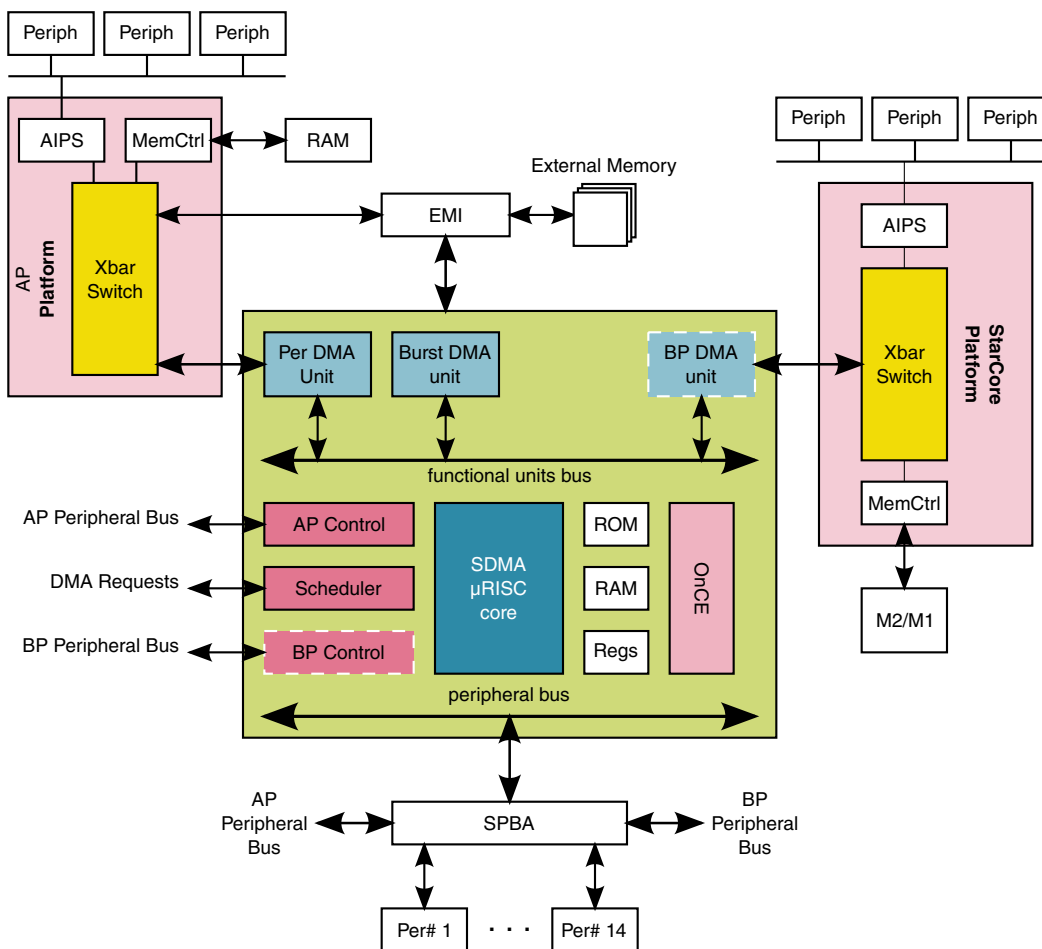

Figure 47-2. SDMA Connections

47.4.1 SDMA Core

The SDMA core is a customized RISC-like processor that is specifically developed to control DMA units and perform L1 tasks like byte-stuffing or framing.

The SDMA core incorporates on-chip debug capability using the OnCE.

The SDMA core is based on a 32-bit register architecture with 16-bit instructions. There are eight general purpose 32-bit registers, four flags (T, LM, SF, and DF), and four PCU registers (PC, RPC, SPC, and EPC) that can address 16,384 16-bit instructions.

47.4.1.1 SDMA Core Structure

The figure found here shows the structure of the SDMA core. It also shows the different registers, calculation resources, and possible data movements.

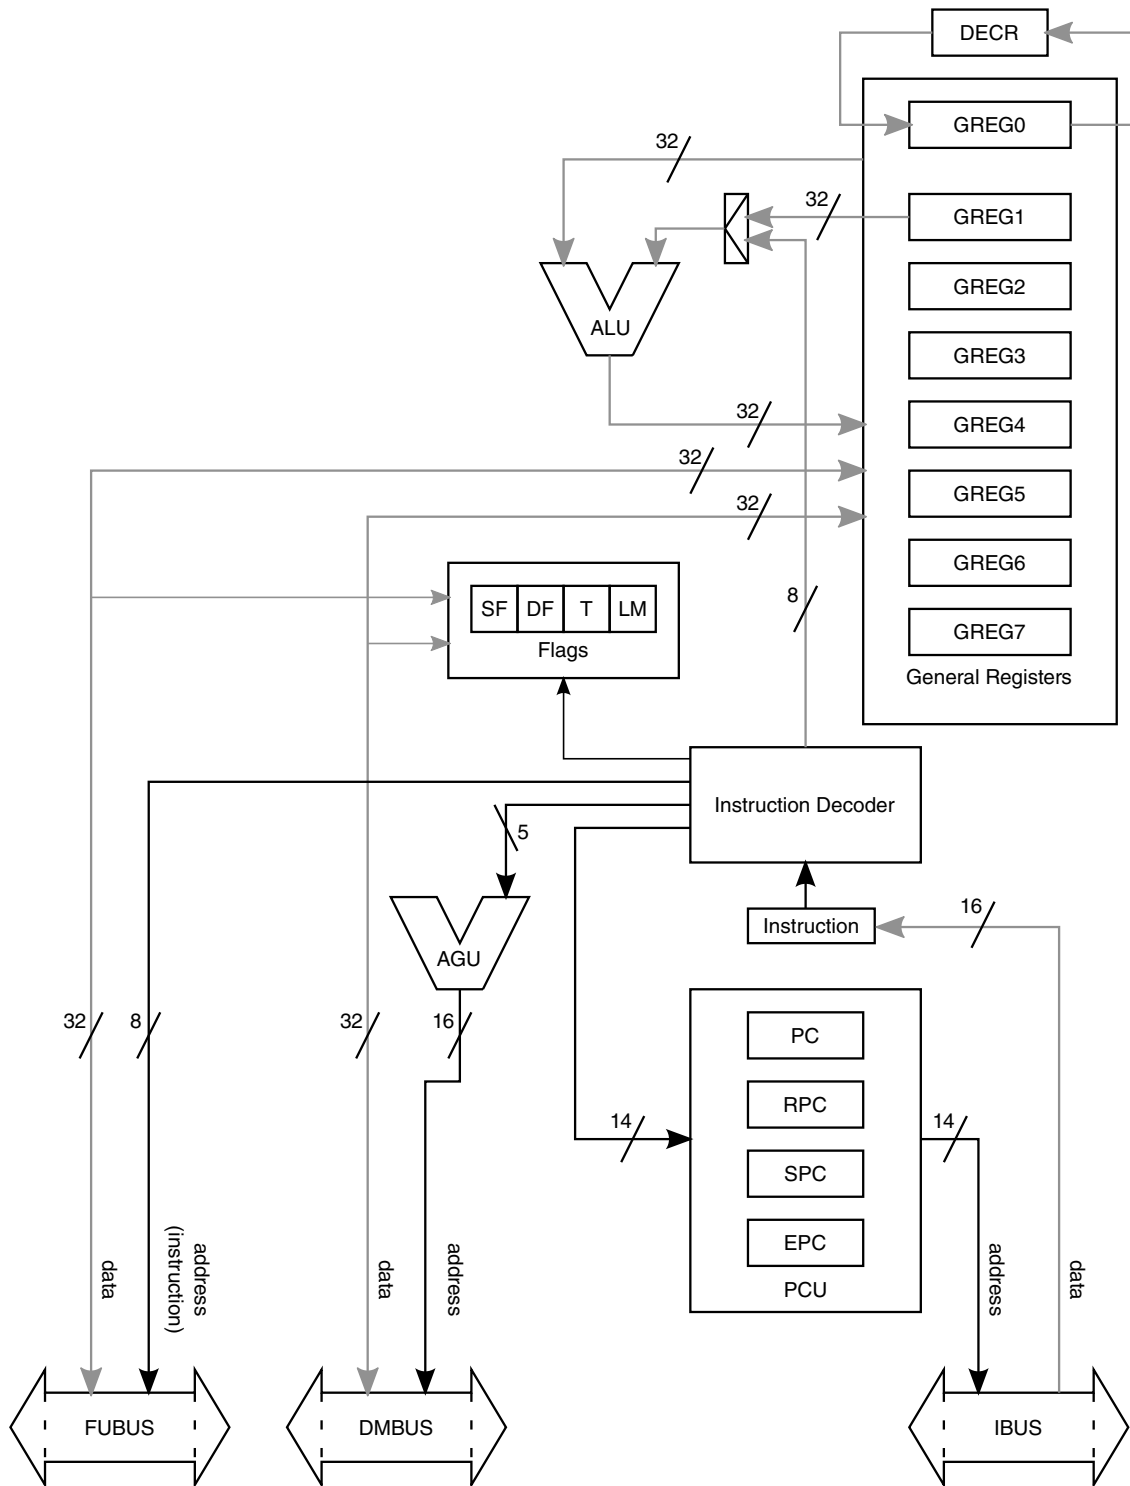

Figure 47-3. SDMA Core

- The Program Control Unit (PCU) is described in [Program Control Unit \(PCU\)](#). It handles the state of the core and generates the instruction fetch addresses. Instructions are retrieved from the Instruction Bus (IBUS) and stored in the SDMA

core instruction register prior to their decoding. The PCU contains the following registers:

- The Program Counter (PC) contains the address of the current instruction.
- The Return Program Counter (RPC) contains the address of the instruction that follows a jump to the subroutine.
- The Start Program Counter (SPC) contains the address of the first instruction of the current hardware loop.
- End Program Counter (EPC) contains the address of the last instruction of the current hardware loop.
- The other core registers are the general purpose registers (GREGn) and the flags.
 - The general purpose registers can be used to hold data and addresses. They can be loaded with immediate values (for example, 8-bit data that are encoded in the instruction), results of calculations that were performed with the ALU, 32-bit data that comes from the memory or peripherals via the Data Memory Bus (DMBUS), 32-bit data that comes from the DMAs via the Functional Units Bus (FUBUS) or another general purpose register. Their content can be the operands of the ALU, the data to send on either bus (DMBUS or FUBUS), or a pointer to memory (DMBUS address).
 - The general register 0 (GREG0) is also the hardware loop counter. In hardware loops, it cannot be used for any other purpose. This register uses a dedicated decrement unit (DECR) shown in [Figure 47-3](#).
 - The flags reflect the status of operations:
 - SF and DF are set when the last load or store on either bus (FUBUS or DMBUS) received an error response.
 - LM is set when the core is executing instructions inside a hardware loop.
 - T is set when the ALU operation result was 0 or the loop counter reaches 0 (the latter is preponderant when an ALU operation is the last instruction of a hardware loop).
- The ALU has two operands: any general register and either a second general register or an immediate value. The result is always stored into the first general register. A NOP function can be utilized by moving a register's contents into itself (For example, the instruction: mov R0,R0).
- The 16-bit instructions are fetched via the instruction bus (IBUS) whose address is driven by the PC. The SDMA RAM and ROM are visible to the core as 16-bit devices through this interface.
- The memory (RAM and ROM), memory mapped registers, and external peripherals are accessed via the DMBUS. The address is always taken from a general register whose content is added to a 5-bit immediate value. This is the only available addressing mode. The DMBUS is a 32-bit data bus. Except for the peripherals that

are external to the SDMA, the address accuracy is the 32-bit word (for example, adding 1 to an address points to the next word, not the next byte).

- The functional units are accessed via the FUBUS connection. The data is exchanged with any general register, but the address (which in fact is the instruction and the selector of the functional unit) comes from an 8-bit field of the corresponding load or store.

47.4.1.2 Program Control Unit (PCU)

This part of the SDMA core is dedicated to the control of the RISC engine, as implied by the instructions that are executed. Its behavior is determined by the instruction type and the inputs of the SDMA.

It contains the PC, RPC, SPC, and EPC registers that are described in [SDMA Core Structure](#).

47.4.1.2.1 Instruction Types

The state sequence and the delay of execution vary according to the type of the instruction. There are six possible categories of instructions, as follows:

1. Standard: Most of the instructions belong to this category, and always last 1 cycle.
2. ldf/stf: These are respectively the load and store instructions that access the functional units. They last $1+n$ cycles where n is the number of wait-states of the targeted functional unit.
3. ld/st: These are the load and store instructions that access the memory and peripherals. They last $1+n$ cycles where n is the number of wait-states of the targeted device (1 for the ROM, RAM, and memory mapped registers, 1 + the external peripheral wait-states). These instructions always last at least two cycles, but the core is able to handle them in one cycle. The first wait-state is inserted outside the core.
4. Branch: These are all the instructions that cause the Program Counter to point to another instruction other than the following one (for example, one that breaks the sequential flow). There are the absolute jumps, the conditional branches, the jump to the sub-routines, and the return from the sub-routine.
5. Loop, Modified Load or Store: The hardware loop instruction modifies the potential behavior of any load or store inside the loop (for example, when the LM flag is set). A jump may be implied after any such load or store if it received an error. The error causes an early exit of the loop, which means a jump to the instruction that follows the one that is pointed to by EPC. An additional cycle is required by the PCU to perform the jump (+1 to the ld/st/ldf/stf original execution delay). Although there is

usually an implicit jump after the last instruction of the loop when the PC goes back to SPC, this is performed at no cycle cost.

6. Done: The done, yield, or yieldg instructions are used to control channel switching. When no channel switching is performed, these instructions last a single cycle. When there is a change of channel or context switch, the delay is variable and depends on many factors (as detailed in [Context Switching](#)).

47.4.1.2.2 PCU States

The PCU state is visible through outputs of the SDMA (see [Real-Time Debug Outputs](#)) or the OnCE status register(see [OnCE Status Register \(OSTAT\)](#)).

The PCU state is a four-bit field that can take the values shown in the following table. [Figure 47-4](#) shows the possible state transitions and the corresponding conditions.

Table 47-3. PCU States

Value	State	Description
0	Program	This is the usual instruction cycle.
1	Data	This state is inserted when there are wait-states during a load or a store on the data bus (ld/st type).
2	Change of Flow	This is the second cycle of any instruction that breaks the sequence of instructions (branch and done types). This state lasts only a single cycle; it is always followed by the Program state.
3	Error in Loop	This state is used when an error causes a hardware loop exit (loop-modified load or store type). This state only lasts a single cycle; it is always followed by the Program state.
4	Debug	The SDMA is stopped in debug mode.
5	Functional Unit	This state is inserted when there are wait-states during a load or a store on the functional units bus (ldf/stf type).
6	Sleep	No script is running: The core is idle after saving the last channel context.
7	Save	The context switch FSM is saving the current channel.
8	Program in Sleep	Same as Program except there is no associated channel, this state is used when instructions are executed after entering debug mode, whereas the core was in either Sleep mode.
9	Data in Sleep	This is the same as Data except there is no associated channel.
10	Change of Flow in Sleep	This is the same as Change of Flow except there is no associated channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
11	Error in Loop in Sleep	This is the same as Error in Loop except there is no associated. channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
12	Debug in Sleep	This is the same as Debug except the core was put in debug mode when no channel was active.
13	Functional Unit in Sleep	This is the same as Functional Unit except there is no associated channel.

Table continues on the next page...

Table 47-3. PCU States (continued)

Value	State	Description
14	Sleep after Reset	This shows that no script is running, and the core is idle after a reset. When a channel becomes active, no context is restored but the core starts its boot program located at address 0 (or the address available in register in Channel 0 Boot Address (SDMAARM_CHN0ADDR)).
15	Restore	The context switch FSM is restoring the next channel context.

Figure 47-4. PCU State Diagram

47.4.1.3 SDMA Core Memory

The SDMA has two memory spaces: one for the instructions and one for the data. As both spaces share the same resources (ROM and RAM devices), the system bus manages possible conflicts when the core accesses the same resource for both an instruction read and a data read or write.

Program and data memory is further described in [Address Space](#).

Instructions of 16-bit width are stored in 32-bit wide devices and can be accessed as data. The mapping is Big Endian: an even instruction address (terminated by 0) accesses the most significant part of the 32-bit data (bits [31:16]), and an odd instruction address (terminated by 1) accesses the least significant part of the 32-bit data (bits [15:0]). Instructions can be fetched out of internal ROM or RAM.

Data can be read from ROM, RAM, memory mapped registers, and external peripherals, and written to the same devices (except the ROM).

The ROM contains bootload scripts, channel scripts, and common subroutines which may be referenced by channel scripts elsewhere in the ROM or RAM.

The RAM is divided into a context area and a code space area which may be used to store channel scripts. The RAM contains undefined values after a hardware reset. Channel scripts and initial context values are downloaded into RAM using channel 0 which is reserved for bootload functions.

47.4.2 Scheduler

All channel scheduling hardware is included in the Scheduler.

47.4.2.1 Primary Functions

The scheduler is a hardware-based design used to coordinate the timely execution of 32 virtual DMA channels by the SDMA core on the basis of channel status and priority.

The scheduler performs the following functions:

- Monitors, detects, and registers the occurrence of any one of the 48 DMA requests
- Links a specific request to a channel or group of channels (channel mapping)
- Ignores requests that are not mapped to a previously configured channel
- Maintains a list of all the channels that are requesting service

- Assigns a pre-programmed priority level (1 of 7) to every channel requesting service
- Detects and flags overrun/underrun conditions

47.4.2.2 Channels and DMA Requests

47.4.2.2.1 Channels

A Virtual Channel (hereafter simply called a channel) manages a flow of data through the SDMA. Flows are typically unidirectional.

The SDMA can have up to 32 simultaneously operating channels, numbered from 0 to 31. Channel 0 is usually dedicated to control the SDMA script downloading. All the channels can be assigned by the ARM platform software.

47.4.2.2.2 DMA Requests

A DMA request is caused by externally (for example, external to the SDMA) controlled conditions (for example, UART receive FIFO reaches a threshold). The SDMA currently supports up to 48 DMA requests.

47.4.2.2.3 Mapping from DMA Requests to Channels and Priorities

A channel can stall waiting on a single DMA request. A single DMA request can awake more than one channel (in fact, any request can awake any combination of channels).

The mapping between DMA requests and channels is program-controlled. There is a storage element assigned for each of the 48 requests that contains a bitmap table of the channels that are awakened by the event.

Every channel also has a three-bit register that indicates its priority.

47.4.2.3 Scheduler Functional Description

[Scheduler Overview](#) describes the behavior of the SDMA scheduler-from the channel enabling conditions to the highest priority pending channel selection.

47.4.2.3.1 Scheduler Overview

The scheduler algorithm is built in hardware. It is provided with possibilities for the ARM platform to control its behavior.

The scheduler processes incoming DMA requests, maps detected requests to 0, one, or several channels, maintains a list of channels that are requesting service (pending channels), identifies the top priority and its associated channel, and selects the next active channel when the current channel yields.

The following figure shows a functional overview.

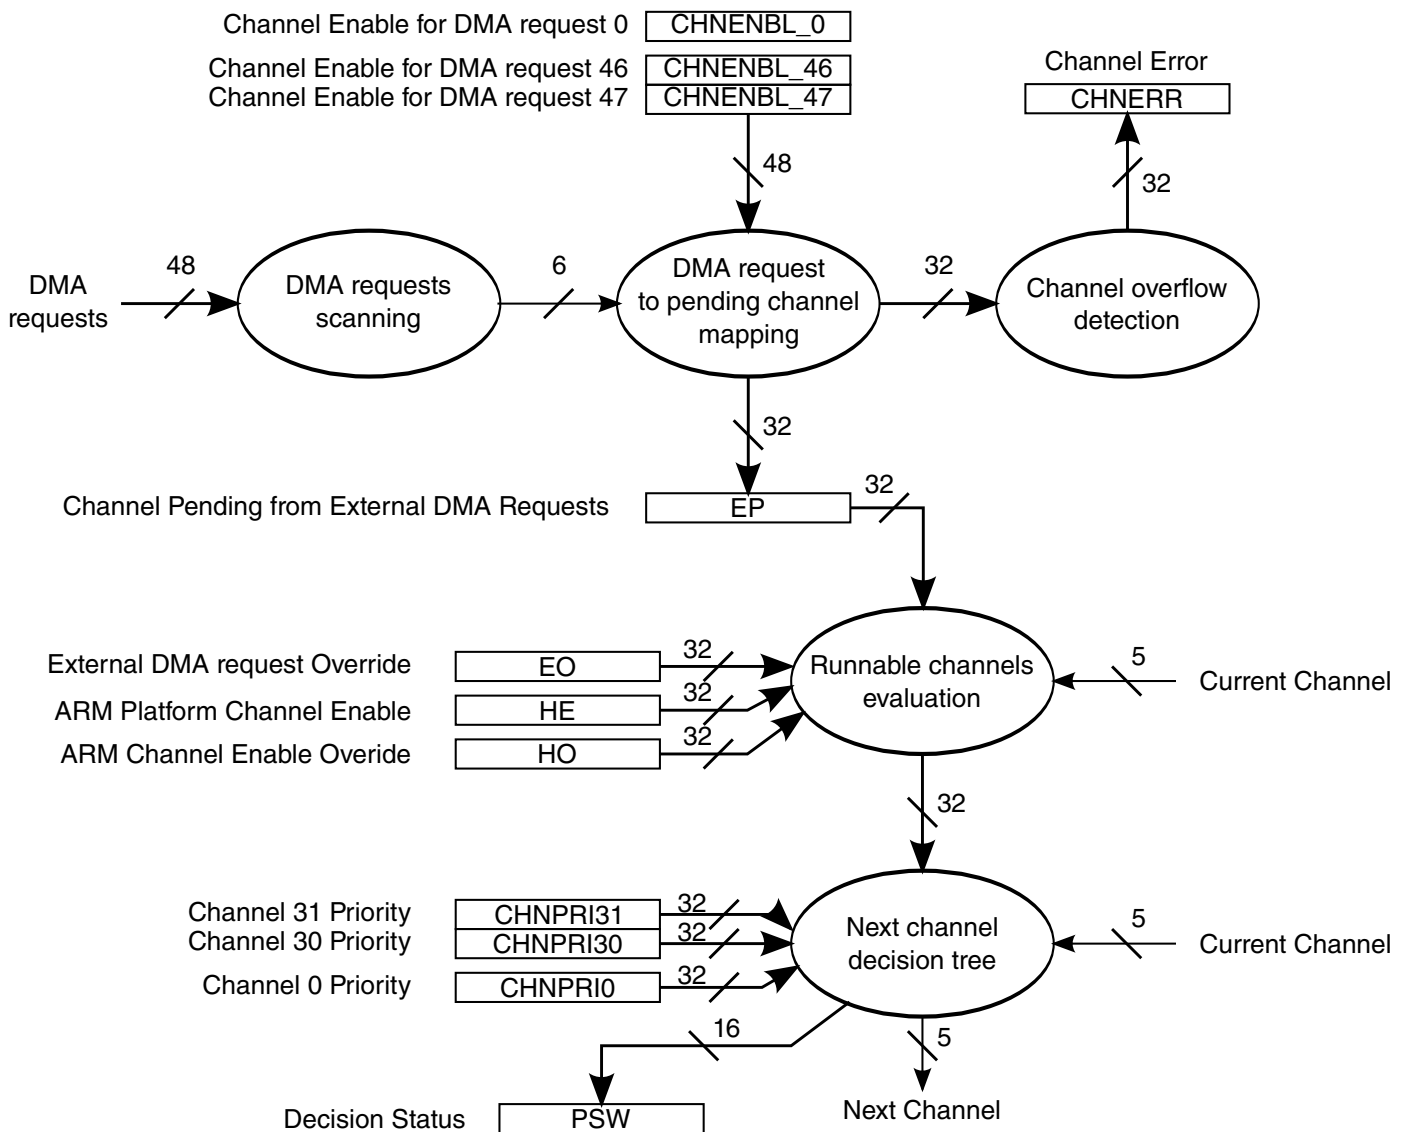

Figure 47-5. SDMA Hardware Scheduler

47.4.2.3.2 DMA Requests Scanning

The scheduler contains a 48-bit edge detection device that detects the rising edge of every DMA request and transmits the request number to the next stage.

The DMA requests are assumed to be generated on the same reference clock as the SDMA core clock; they are detected as soon as the signal goes from a 1-to-n-cycles low state to a 1-to-m-cycles high state.

This system is able to detect single-cycle pulses as well as level-based DMA requests such as a FIFO threshold crossing. In this case, the SDMA provides a memory mapped register that can be used by the channel script to monitor the DMA requests lines, and thus determines whether the data transfer is done or not done, and then continues with the transfer or closes the channel.

When several DMA requests are detected at the same time, they are forwarded to the next scheduler stage at the rate of one request per cycle. No request is lost.

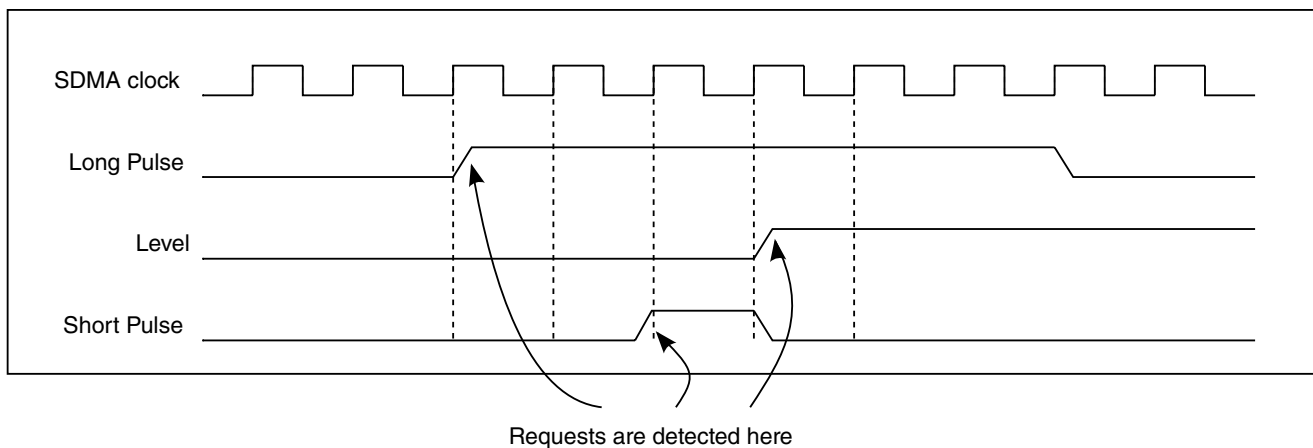

Figure 47-6. Examples of Valid DMA Requests

The DMA request inputs are connected to various sources that depend on the SoC. The exact list of DMA request inputs and their associated number is available in each respective project-specific chapter.

47.4.2.3.3 Mapping DMA Requests to Pending Channels

Whenever a DMA request is detected by the first stage, its number is used in the second stage to determine the channels that have to be activated.

This is performed with an array of 48 registers that are 32 bits wide: There are 48 Channel Enable Registers (CHNENBLn), one register per DMA request. The DMA request number selects the Channel Enable Registers, and every bit of this 32-bit register indicates that the corresponding channel must be activated when it is a 1.

Functional Description

This information is passed on the EP register. For every bit of the Channel Enable Register that is set, the corresponding bit of the EP register is also set, and the remaining bits of EP are left unchanged. The transformation of EP is summarized by the following equation:

$$EP = EP \text{ or } CHNENBLn$$

The EP register is used to know which channels require service because they received a DMA request.

Typical contents of the CHNENBLn registers are all 0s, except for a single bit set. For example, a DMA request triggers one channel, but all 0s or several 1s are possible. One DMA request could activate several channels, and the channel execution sequence can be controlled by the channel priorities and numbers, as explained in the next sections. The following table illustrates an example configuration.

NOTE

From the table, the DMA request 0 is programmed to simultaneously trigger channels 0, 1, and 31. Also, DMA requests 30-47 are not used in this example. The remaining channels 2 to 30, are configured to be triggered by DMA requests 29 to 1, respectively.

Table 47-4. Channel Enable RAM Programming Example

DMA Request Number	Channel

47.4.2.3.4 Channel Overflow

A channel overflow occurs when a DMA request requires service from channel *n* by setting bit *n* of the register EP, but this bit is already set, meaning channel *n* is already pending. This can come from an overrun/underrun condition.

This detection is possible only when the DMA requests are pulses, because a level-based DMA request stays high until it is serviced, even though an underrun or overrun condition occurs, thus preventing another edge detection of the DMA request.

The channel overflow information is saved in the 32-bit CHNERR register (1 bit per channel). You can configure the SDMA to trigger an interrupt to the ARM platform when there are 1s in CHNERR. Every bit of CHNERR is masked with the corresponding bit of INTRMASK and if it gives a 1, the corresponding bit of INTR is set, triggering the interrupt.

47.4.2.3.5 Runnable Channels Evaluation

The EP register is used in conjunction with several other 32-bit registers to determine the channels that are runnable.

Registers EO, DO, HO and HE, are controlled by the ARM platform. EP is controlled by the DMA requests and their mapping to channels.

Several channels may be runnable at any given time. The *i*th channel is runnable if (and only if) the condition below is true:

$$(HE[i] \text{ or } HO[i]) \text{ and } (DO[i]) \text{ and } (EP[i] \text{ or } EO[i])$$

After reset, the HE[i], HO[i], EP[i], and EO[i] bits are all cleared whereas the DO[i] bits are all set. The functions associated with DO are not available for this device. When DO[i] is set, the scheduler condition becomes:

(HE[i] or HO[i]) and (EP[i] or EO[i])

The registers in these equations are controlled as follows:

- ARM platform (host) channel enable flag HE[i] may be set or cleared by the ARM platform with the HSTART and STOP_STAT registers. It can also be cleared by the i^{th} channel script.

Typical usage is for the ARM platform to set this flag to activate the channel. The flag is cleared by the SDMA core when the transfer is done.

- Externally triggered channel pending flag EP[i] is set by the scheduler when the channel was activated by a DMA request. It can be cleared by the i^{th} channel script.
- The ARM platform channel override flag HO[i] may be set or cleared by the ARM platform. When set, it enables the i^{th} channel to run without the involvement of the ARM platform.

Typical usage is for the ARM platform to set this flag for channels that do not need ARM platform supervision such as channels that are controlled by DMA request events (EP).

- DO should always be set to 1 so that the runnable channel evaluation considers only HO, HE, EP, and EO.
- Externally triggered channel override flag EO[i] may be set or cleared by the ARM platform. When set, it prevents the i^{th} channel from stopping and stalling on incoming peripheral DMA requests. This is the case when the channel is not handling data transfers with peripherals (for example, a memory to memory transfer).

The SDMA can clear the HE[i], and EP[i] bits by means of a done or notify instruction. The done instruction causes a reschedule; thus, enabling another channel to preempt the current one, while the notify instruction does not. The done and notify instructions can clear either HE[i] or EP[i] (never more than one at a time).

Table 47-5. Runnable Channel Selection Control

Register	Set by	Cleared By
HO	Write to HOSTOVR register	Write to HOSTOVR register
HE	Write to HSTART register	Write to STOP_STAT register or by the channel script with the done or notify instructions.
DO	Write to DSPOVR register	Write to DSPOVR register
EO	Write to EVTOVER register	Write to EVTOVER register
EP	Set by external DMA request event input.	By the channel script with the done or notify instructions

47.4.2.3.6 Next Channel Decision Tree

The next channel number is computed from the runnable channels list, the current channel number, and their respective priorities.

It is re-evaluated every cycle, but is only used when the current channel yields or terminates by executing a yield, yieldge, or done instruction.

The decision tree is based on the selection of the runnable channel that has the highest priority.

The highest priority channel is selected according to the following rules:

- Runnable channels are sorted by priority.
- If one of the channels with the highest priority had been preempted by a channel with a higher priority, but did not want to yield to a channel of the same priority (for example, it executed a yield, not a yieldge), it is elected as the next channel.
- The channels that belong to the highest priority group are sorted by their number and the channel that has the highest number in this group becomes the next channel. For example, if priorities are the same, channel 31 will be selected before channel 30.

When the current channel requires a reschedule with a yield(ge) or a done instruction, the context switch decision is based on the instruction parameter, the current channel number and priority, and the next channel number and priority. The possible cases are all listed in the following table. The grayed cells correspond to unusual cases that should not occur with a typical usage of the SDMA.

Table 47-6. Channel Switching Decision with a yield, yield(ge), or done

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
yield (done 0)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Current
			Current < Next	Next ¹
	Not runnable	Not runnable	none	none ² (occurs when the channel was disabled by the ARM platform)
	Not runnable	Runnable	none	Next ¹ (occurs when the channel was disabled by the ARM platform)
yieldge (done 1)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Next ¹
			Current < Next	Next ¹

Table continues on the next page...

Table 47-6. Channel Switching Decision with a yield, yield(ge), or done (continued)

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
	Not runnable	Not runnable	none	none ² (occurs when the channel was disabled by the ARM platform)
	Not runnable	Runnable	none	Next ¹ (occurs when the channel was disabled by the ARM platform)
done (done>1)	Not runnable	Not runnable	none	none ²
	Runnable	Not runnable	none	Current ³ (occurs when the done instruction does not disable the channel runnable condition)
	Not runnable	Runnable	none	Next ¹
	Runnable	Runnable	none	Current ³ (occurs when the done instruction does not disable the channel runnable condition)

1. Current channel script execution is stopped, its context is saved; the next channel context is restored and its script execution resumes
2. Current channel context is saved and SDMA enters IDLE mode
3. Current channel context is saved, then restored, and the current channel script resumes execution

Finally, when the SDMA is in IDLE mode and a runnable channel is elected as the next channel, its context is immediately restored and the script execution resumes.

The *combinatorial-decision* tree supports dynamic modifications of the EP, EO, HE, HO, and DO flags as well as dynamic modifications of the channel priorities. The propagation times are detailed in [Scheduler Pipeline Timing Diagram](#).

The decision tree status is available in the PSW register, which is continuously updated. It contains the next channel priority, the next channel number, the current channel priority, and the current channel number. When a priority is read as 0, it means the channel is not runnable.

A few examples of decisions are presented below:

- Channel 31 is running with priority 5, channels 13 and 24 are pending with the same priority 5; channel 24 is eligible as the next channel since $24 > 13$.
- Channel 31 is running with priority 7, channels 13 and 24 are pending with priority 5; channel 31 is the next channel because its priority is greater than the other pending channels.
- Channels 7, 23, and 29 are pending with the same priority. Channel 7 is active and runs a yieldge; it is preempted by channel 29. After a period of time, channel 29 runs a yieldge, it is then preempted by channel 23 that is the selected channel since channel 29 is the current channel. Later, channel 23 runs a yieldge and is preempted

Functional Description

by channel 29. Channels 23 and 29 will go on switching after every yield until one of them terminates. It is only at that point that channel 7 becomes eligible again.

- Channel 11 is running with priority 3, and channel 15 is pending with priority 4. When the channel 31 script executes a yield instruction, it gets preempted by channel 15; then channels 6 and 18 with priority 3 become pending. Because channel 11 was preempted after executing a yield and there is no pending channel with a strictly greater priority, it is eligible as the next channel (although its number $11 < 18$).

47.4.2.3.7 Scheduler State Diagram

The [Figure 47-7](#) summarizes the behavior of the SDMA scheduler with details about the exact mechanism of the priority decision tree. It is important to understand the scheduler is a hardwired pipeline, which means all the stages are performed simultaneously every cycle, but a change on any given stage is reflected on the next stage after the delays presented in [Scheduler Pipeline Timing Diagram](#).

Figure 47-7. Scheduler State Diagram

47.4.2.3.8 Scheduler Pipeline Timing Diagram

The SDMA scheduler process of DMA-request and control-register modifications is not immediate.

The figure below shows the exact delays of all the tasks. The reference clock is the SDMA core clock.

Figure 47-8. Scheduler Timing Diagram

Two numbers can be inferred from this timing diagram. First, it takes six SDMA core clock cycles to update the next channel from a DMA request. Second, it takes three SDMA core clock cycles to update the next channel from a direct modification of the condition registers (EP, DO, HE, or HO) by any processor. The processors that can modify these bits include SDMA with a done instruction or the ARM platform with a write access through the corresponding control port on their respective peripheral bus).

47.4.2.3.9 Channel-DMA Request Mapping

The 48 DMA request inputs to the SDMA scheduler are listed in project-specific chapters. Refer to the respective chapters for this information.

47.4.2.3.10 Examples: How to Start a Channel

A channel can be started when the following equation is true for channel *i*:

(HE[i] or HO[i]) and (DO[i]) and (EP[i] or EO[i])

Once this equation is true, the scheduler can start this channel according to the priority of all pending channels. Several examples of configuration are listed below:

1. To start a channel triggered by ARM platform software:
 - Initially, configure HO[i]=0, DO[i]=1, and EO[i]=1 using registers indicated in [Table 47-5](#).
 - ARM platform software triggers the channel by writing to the HSTART register to set HE[i]=1, thereby setting the above equation true.
2. To start a channel triggered by DMA request event.
 - Initially, configure HO[i]=1, DO[i]=1, and EO[i]=0 using registers indicated in [Table 47-5](#).
 - The DMA request is asserted to trigger the channel by setting EP[i]=1, which makes the above equation true.

47.4.2.4 Context Switching

On execution of a done or yield(ge) instruction, the current channel may be changed either because it has finished (which necessarily happens when the done instruction is executed), or it was preempted by a higher priority channel (which is possible but not systematic when the yield(ge) is executed).

Upon a channel change the SDMA goes through a context switch procedure.

When the current channel yields or ends, the context for that channel is saved into the context RAM locations for that channel. When the next channel starts running, its context is first restored from RAM.

Since context RAM is not yet initialized by reset, there will be no context restore at the beginning of the first channel (bootload channel) run after reset. It is expected that the bootload channel will be used to initialize the context for all other channels. When the bootload channel finishes running or yields, SDMA will enter its SAVE state and save that channel's context into RAM. Then, if the bootload channel is called again later, the context will be restored from RAM when the channel starts again.

The context structure for each channel is defined in [Context Switching-Programming](#) and [Table 47-11](#). There will be one context area reserved for each channel. When a channel ends or yields, the SDMA core registers are automatically saved into the context RAM and later restored from the context RAM when the channel is next run. The total RAM space reserved for 32-channel contexts is either 3K or 4K depending on whether the SMSZ bit is set in the CHN0ADDR register, which enables an additional 8 words of scratch RAM for each context.

47.4.2.4.1 Context Switch Modes

The exact procedure to save the context of the old channel, and to restore the context of the new channel depends on the context switch mode selected by the ARM platform in the CONFIG control register.

The following are the context switch modes:

- By default, the "dynamic" context switch is set. This mode provides the most efficient context switch for an average of eight cycles to stop the current channel, save its context, restore the next channel context, and resume its execution. It consists of saving modified registers of the current channel in the background (for example, during the channel execution)-which leaves very few registers to save when the switch is decided-resuming execution of the next channel as soon as possible (for example, when the minimal set of registers is restored), and continuing the restore phase during this execution.
- In "dynamic with no loop" mode, the same principle is followed except the modified registers are only saved in the background when the loop flag is not set. This mode offers almost the same effectiveness as the previous one, but it prevents the system from accessing the RAM during loops to save power. This is the recommended mode for an efficient context-switch when the loop bodies are short.
- In "dynamic power" mode, no background saving is performed, which reduces power consumption to the minimum. The modified registers are only saved when the context switch starts. The restore phase is the same as before. This is the mode that achieves the optimal power consumption at the cost of a slower context-switch.
- In a "static" context switch, all the registers are saved when a context switch is decided, and all the registers are restored before starting the execution of the new channel. This mode enables a predictable behavior of the context switch since all the registers are restored prior to the channel start and all registers are saved after the channel termination.

NOTE

Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized during the context SAVE phase when the channel is done or yields. Subsequent calls to the same channel or different channels may use any of the dynamic context modes. This will ensure that all context locations for the bootloader channel are initialized, and prevent undefined values in context RAM from being loaded during the context restore if the channel is re-started later.

47.4.2.4.2 Context Switch Procedure

The Program Control Unit goes into the *save* state, the current context is spilled into memory, and the next channel context is restored according to the context-switch mode that was selected by the ARM platform.

The context switch procedure is as follows:

1. Load the current context's spill base address.
2. Spill the modified registers of the current channel to memory according to the selected context switch mode while the channel is running.

On a *done* or *yield(ge)* that causes the channel preemption, the PCU goes into the *save* state. In *static* mode, all the registers are saved; whereas, in either *dynamic* mode, the registers that were modified but not yet saved are then saved, and the PCU registers and flags are finally saved.

3. Put the SDMA core into *sleep* and wait for new channels to be serviced. This step is skipped if there are pending channels when the current channel is saved.

As soon as there is at least one pending channel, the PCU goes into its *restore* state to restore the context of the channel that was elected by the scheduler.

Once a channel is elected, it remains the current channel until its script requests a rescheduling operation with a *done* or *yield(ge)* instruction. That means the current channel cannot be modified by the ARM platform, even if it is no more runnable or if its priority is modified.

The ARM platform can however force a reschedule by writing the corresponding bit in the CONFIG register, which has the same effect as if the script had executed a *done* instruction. That feature should only be used to stop the SDMA in emergency cases.

4. Load the context base-address of the new channel.

In "static" mode, all the registers are restored. In either "dynamic" modes, only the PCU registers are restored.

The new channel is running. In "static" mode, no more activity regarding context restoring or saving is performed. In either "dynamic" modes, the registers are restored in the background every time an access to the context RAM is possible, and priority is given to restoring the registers that are required by the next instruction to be executed. When a register has not been restored and the next instruction needs it, this instruction gets stalled until the register was restored.

In "dynamic" and "dynamic with no loop" modes, background saving of dirty registers is performed every time an access to the context RAM is possible and allowed by the context switch mode.

NOTE

The contents of a channel context space in the context RAM depends on the selected context switch mode. In "dynamic" and "dynamic with no loop" modes, the contents of the context RAM tend to match the contents of the SDMA registers (except for the PCU registers and flags that are never saved in the background). In "dynamic power" and "static" modes, the contents of the context RAM remain unchanged until the channel terminates with a done or gets preempted.

47.4.2.4.3 Context Map in Memory

Refer to [Context Switching-Programming](#).

47.4.3 Functional Units

The functional units are small systems that are used by the SDMA core to handle data transfers between the core and a bus domain external to the SDMA.

The SDMA core is able to control and exchange data with these systems by sending instructions and reading or writing data from/to the functional units' registers via the FUBUS. This is done with the ldf and stf instructions.

The following sections provide introductions to the available functional units. [Functional Units Programming Model](#) provides descriptions the functional units' behaviors.

47.4.3.1 Burst DMA Unit

The burst DMA unit enables the SDMA core to perform data transfers to and from the ARM platform memory.

It is optimized for accessing SDRAM-like devices. It does not provide control to assign a privilege level to the DMA access. The burst DMA unit provides the SDMA with means to do the following:

- Perform up to 8-beat read and write bursts to the ARM platform memory, which optimizes throughput when accessing SDRAM-type devices because of an internal, 36-byte FIFO
- Access the ARM platform memory at once or twice the SDMA core frequency
- Copy data from one ARM platform memory location to another ARM platform memory location at the ARM platform bus speed, which provides a very high throughput
- Control the method for addressing the ARM platform memory (automatic increment of addresses or frozen addresses-the former aimed at accessing RAM-like memory and the latter aimed at accessing single-address FIFOs)
- Enable or disable automatic prefetch when reading data from the ARM platform memory. When the prefetch mode is selected, the burst DMA automatically triggers external bursts to fill its FIFO without waiting for the SDMA core to request the corresponding data, greatly improving throughput.
- Rely on the DMA to automatically flush its FIFO content when there is enough data to generate an 8-beat burst to the ARM platform memory. Or, it forces a flush when a data transfer must terminate.
- In the former case, the SDMA core may only be stalled when it tries writing data and there is not enough room left in the FIFO. In the latter case, the core is stalled until the data is effectively written to the ARM platform memory.

In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the ARM platform memory. This error status is retrieved by a later access to the burst DMA.

Terminating a write data transfer with a forced flush command guarantees that any bus error to the ARM platform memory is caught.

- Handle address alignment issues between the ARM platform memory map and the SDMA core data. This enables the core to read or write 32-bit data from the burst DMA, whereas the corresponding ARM platform address is not 32-bit aligned. This drastically improves the SDMA scripts' efficiency since the same loop that transfers 32 bits at a time can be used regardless of the start and end addresses in the ARM platform memory space.

This unit structure and registers are described in [Burst DMA Structure](#) and [Burst DMA Registers](#).

47.4.3.1.1 Burst DMA Structure

The burst DMA is essentially made up of a 36-byte FIFO, address registers, and a controlling state-machine. The 36-byte FIFO enables eight-word buffering with address alignment, and the state-machine manages clock adaptation when required.

The burst DMA is depicted in the figure below.

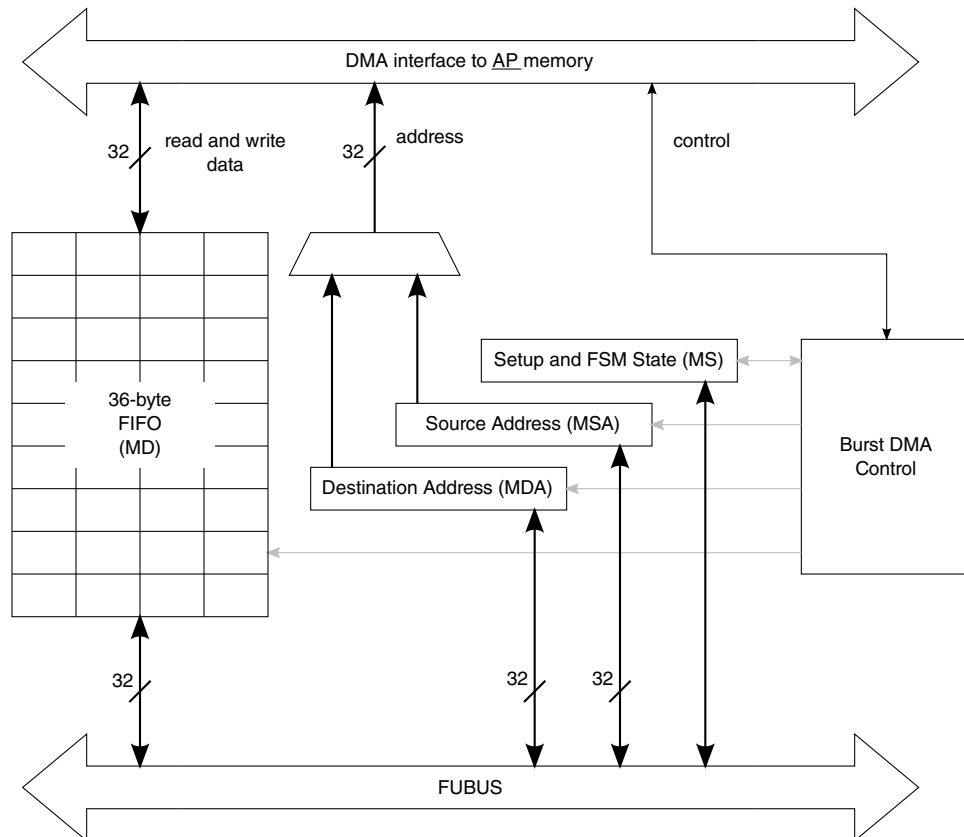

Figure 47-9. Burst DMA Structure

47.4.3.1.2 Burst DMA Registers

There are four registers, as follows, that may be accessed from the SDMA core:

- MSA (Memory Source Address) - Holds the source byte address in the ARM platform memory map for reading data from this location. This register is automatically modified every time the core reads new data from the FIFO.
- MDA (Memory Destination Address) - Holds the destination byte address in the ARM platform memory map for writing data to this location. This register is automatically modified every time the core writes new data into the FIFO.
- MD (Memory Data) - Labels the 36-byte FIFO access point: Reading a byte, halfword, or word from MD respectively retrieves the first 1, 2, or 4 bytes of the

FIFO (for example, the bytes that were stored first by the DMA state-machine when transferring data from the ARM platform memory).

- When the FIFO does not hold as many bytes as required by the SDMA core, the core is stalled until the missing bytes are read from the ARM platform memory. In the case of prefetch mode, the DMA controller decides when it should start a burst to ARM platform memory in order to reduce the risk to not have the required data for the future accesses of the core. When there is no prefetching, a burst is triggered when the required data is not available in the FIFO.

Writing a byte, halfword, or word to MD stores 1, 2, or 4 bytes, respectively, at the end of the FIFO (for example, these bytes are transmitted to the ARM platform memory after all the other bytes that were previously stored in the FIFO). When the FIFO does not have enough room left to hold the written data, the SDMA core is stalled until a sufficient amount of FIFO contents are flushed out to the ARM platform memory. Flushing is decided by the DMA controller when there are enough bytes in the FIFO to perform the largest allowed burst to ARM platform memory (the exact size depends on the burst start address and the AHB 1 Kbyte boundary rule). However, the SDMA core has the ability to force the flushing operation at any time, for example, when at the end of the data transfer, prior to channel closure.

- MS (Memory Setup) - Contains the state of the burst DMA control, the two flags that define whether each address register is incremented after every access to the external memory, and another flag that is set when a bus error occurred.

47.4.3.1.3 Burst DMA Data Transfers

Three typical usages have been identified that involve the burst DMA: the data transfer startpoint, the endpoint, or both.

Every case requires a different procedure, as listed in the following sections:

47.4.3.1.3.1 Data Retrieval from the ARM platform Memory

The following steps retrieve data from ARM platform memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the source address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the source address register itself (MSA).
- Read data from the FIFO using the *ldf MD* instruction as many times as needed. If an error occurred during the fetch from ARM platform memory, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from the FIFO.

47.4.3.1.3.2 Storing Data Into the ARM platform Memory

The following steps store data from ARM platform memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the destination address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the destination address register itself (MDA).
- Store data into the FIFO using the *stf MD* instruction as many times as needed.
- When the transfer is finished and if the DMA worked in automatic flush mode, force the flush of the FIFO. This instruction is stalled until all the FIFO data is effectively sent to the ARM platform memory and the error status of the transfer is available in the DF flag.

47.4.3.1.3.3 Transferring Data Between Two ARM platform Memory Locations-Burst DMA Unit

The following steps copy data between two ARM platform memory locations using the burst DMA unit:

- Set up the MS flags to reflect the modes for the source and destination addresses (all the combinations are possible), then initialize the source address register (MSA) and the destination address register (MDA). Both addresses must be word-aligned.
- Use as many *stf MD* instructions with the *COPY* flag as needed. Every instruction triggers a burst read of a given number of words from the source address (this number is provided to the burst DMA via the SDMA core general purpose register, which is referenced in the *stf* instruction). Once all the data is loaded into the FIFO, the DMA empties it with a write burst of the same count to the destination address. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the burst DMA to check the error status.

47.4.3.2 Peripheral DMA Unit

The peripheral DMA unit is the second functional unit that connects the SDMA to the ARM platform memory.

Unlike the burst DMA, it does not support burst transfers and is optimized for accessing peripherals. It does not provide control to assign a privilege level to the DMA access. Its feature list comprises the following:

- Access to the ARM platform peripherals or memory at once or twice the SDMA core frequency

- Data copy from one ARM platform memory location to another ARM platform memory location at memory bus speed, improving throughput
- Control of the method for addressing the ARM platform memory (automatic increment or decrement of addresses or frozen addresses, the first ones aimed at accessing RAM-like memory and the last one aimed at accessing single-address FIFOs)
- Selectable automatic prefetch when reading data from the ARM platform memory. In prefetch mode, the peripheral DMA automatically fetches another data-without waiting for the SDMA core to request it-when its data register is empty, which improves the throughput
- Selectable automatic flush. In this mode, the SDMA core may only be stalled when it tries writing data and the previous write operation is not finished yet; whereas, in forced flush mode, the core is stalled until the data is effectively written to the ARM platform memory.
- In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the ARM platform memory or the peripheral. This error status is retrieved by a later access to the peripheral DMA. Terminating a write data transfer with a forced flush command guarantees that any bus error to the ARM platform memory has been caught.

This unit structure and registers are described in [Peripheral DMA Structure](#) and [Peripheral DMA Registers](#).

47.4.3.2.1 Peripheral DMA Structure

The peripheral DMA is made up of a 32-bit data register, two address registers, and a controlling state-machine. The state-machine manages clock adaptation, when required.

It is shown in the following figure.

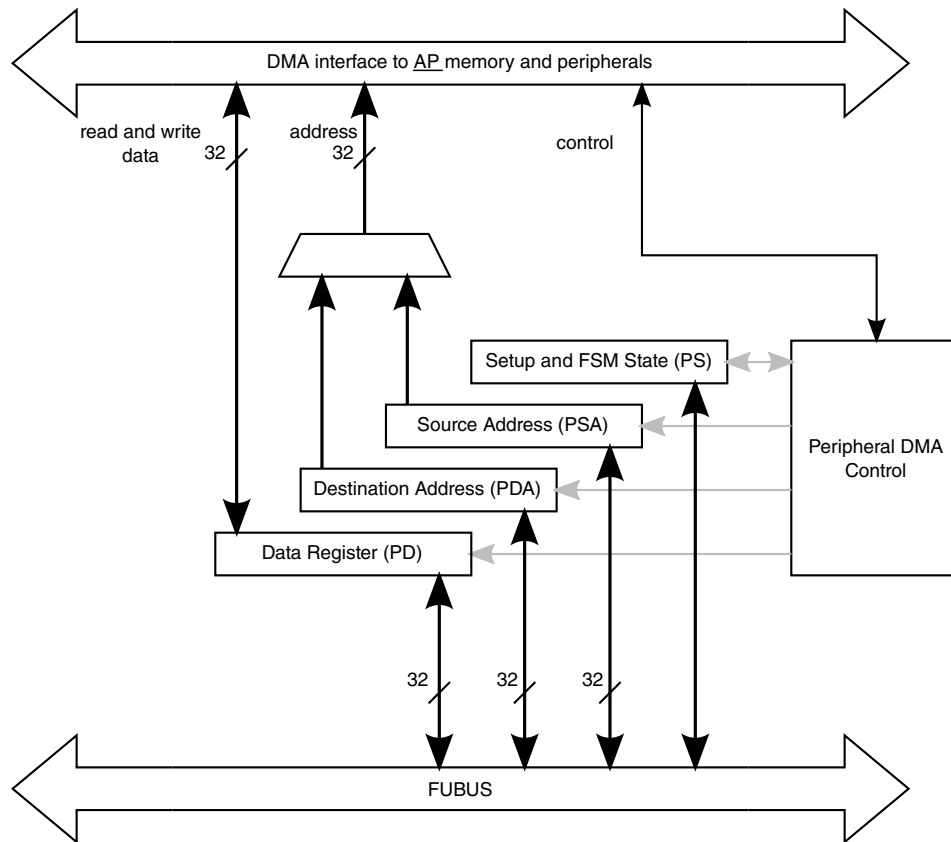

Figure 47-10. Peripheral DMA structure

47.4.3.2.2 Peripheral DMA Registers

According to [Figure 47-10](#), the peripheral DMA has four registers that may be read or written by the SDMA core:

- *PD* (*Peripheral Data*) is the DMA 32-bit data register.
- *PSA* (*Peripheral Source Address*) holds the source byte address in the ARM platform memory map for reading data from this location. This register is automatically modified every time the core reads a new data from PD.

- *PDA (Peripheral Destination Address)* holds the destination byte address in the ARM platform memory map for writing data to this location. This register is automatically modified every time the core writes a new data into PD.
- *PS (Peripheral Setup)* contains the state of the peripheral DMA control, two configuration fields that define the way address registers are modified after every data access, two additional configuration fields that define the data size to access the source and destination devices, and another field that contains the latest transfer error status.

47.4.3.2.3 Peripheral DMA Data Transfers

There are three typical usages that involve the peripheral DMA, whether it is the data transfer start-point, endpoint, or both.

Every case requires a different procedure, as described in [Data Retrieval from the ARM platform Memory or Peripheral](#), [Storing Data into the ARM platform Memory or Peripheral](#), and [Transferring Data Between Two ARM platform Memory Locations-Peripheral DMA Unit](#).

47.4.3.2.3.1 Data Retrieval from the ARM platform Memory or Peripheral

The following steps retrieve data from ARM platform memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the source (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the source address register itself (PSA) with an address that is aligned to the programmed data size.
- Read data from PD using the ldf PD instruction as many times as needed. If an error occurs during the fetch from the ARM platform memory or peripheral, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from PD.

47.4.3.2.3.2 Storing Data into the ARM platform Memory or Peripheral

The following steps store data to ARM platform memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the destination (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the destination address register itself (PDA) with an address that is aligned to the programmed data size.

- Store data into PD using the *stf PD* instruction as many times as needed.
- When the transfer is finished and if the peripheral DMA worked in automatic flush mode, force the flush of PD. This instruction is stalled until PD contents are effectively sent to the ARM platform memory or peripheral, and the error status of the transfer is available in the DF flag.

47.4.3.2.3.3 Transferring Data Between Two ARM platform Memory Locations-Peripheral DMA Unit

The following steps copy data between two ARM platform memory locations using the peripheral DMA unit:

- Set up the PS fields to reflect the modes and data size for the source and destination addresses (all the combinations of addressing modes are possible, but both data sizes must be identical), then initialize the source address register (PSA) and the destination address register (PDA). Both addresses must be aligned with the programmed data size.
- Use as many *stf PD* instructions with the *COPY* flag as needed. Every instruction triggers a single read from the source address; a single write of the received data immediately follows. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the peripheral DMA to check the error status.

47.4.4 SDMA Security Support

The SDMA provides support to SDMA software to block unauthorized updates to the scripts in RAM.

SDMA supports the following Security modes:

- Open Mode: has full control to load scripts and context into SDMA RAM. This is the default mode.
- Locked Mode: The ARM platform loads scripts and channel contexts at startup when it is still executing known safe software. When finished, it locks the SDMA to prevent further updates to RAM and selected registers. More details described in [Locked Mode](#).

47.4.4.1 Locked Mode

The LOCK bit in the SDMA_LOCK register provides support for SDMA scripts to freeze RAM contents after the initial bootload routine to prevent future unauthorized updates to SDMA RAM.

After initial RAM contents are uploaded, ARM platform software can set the LOCK bit to secure the RAM contents to prevent future updates by an unauthorized. After the LOCK bit is written with a '1', the SDMA is "locked" until reset.

The LOCK bit can be read in the SDMA's internal memory map in the LOCK register (see Section [SDMA LOCK \(SDMAARM_SDMA_LOCK\)](#)). SDMA scripts which load information into RAM can check the value of the LOCK bit to determine if an upload to RAM is allowed. If not allowed, the script can refuse to allow the request to copy data into the RAM to continue. The exact use of the LOCK bit in SDMA scripts for security control will be described in SDMA software documentation (see [SDMA Scripts](#)).

While SDMA is locked, attempts to write to the SDMA_LOCK, CHN0ADR, ILLINSTADDR, and ONCE_ENB registers will be ignored. All registers remain readable. Writes to other registers are still allowed.

Once the SDMA is locked, the LOCK bit can only be cleared by a reset. A hardware reset will always clear the LOCK bit. A software reset initiated by writing to the RESET register will only clear the LOCK bit if the SRESET_LOCK_CLR bit in the SDMA_LOCK register is set. Since SDMA_LOCK register cannot be updated if SDMA is locked, the SRESET_LOCK_CLR bit must be configured before setting the LOCK bit. The SRESET_LOCK_CLR bit will also be cleared by resets that clear the LOCK bit.

The SDMA RISC core uses the ILLINST and CHN0ADDR registers as pointers to determine where to jump to after an illegal instruction or upon boot after a reset. The LOCK bit prevents updates to these registers to protect against unauthorized changes to these pointers.

While SDMA is locked, the ONCE_ENB register cannot be written to prevent the OnCE under ARM platform control from being used to gain access to SDMA internal memory. If ARM platform control of the OnCE is enabled before setting the LOCK bit, the ARM platform can use the ONCE for debug purpose after LOCK is set.

47.4.5 OnCE and PCU Debug States

The SDMA has two different debug modes in which the OnCE performs debug instructions.

Refer to [Figure 47-4](#) for an example of the PCU states in debug. The following are the two debug states:

- When a channel is running (that is, when CCR and CCPRI are different from 0, which can be read in the PSW register), SDMA can execute a SoftBkpt instruction from the channel script or receive a debug request. When either happens, the SDMA enters its "Classical" *Debug* state, which is described in [OnCE and Real-Time Debug](#).
- When a channel is not running, the SDMA can be in *Sleep* state or in *Sleep after Reset* state. If a debug request is sent to the core, it enters its *Debug in Sleep* state. This debug mode works similarly to the "Classical" *Debug* state, except it returns to the original state (*Sleep* or *Sleep after Reset*) when the debug mode is left via the `exec_core` instruction of the OnCE. From this *Debug in Sleep* state, the SDMA can execute a program whereas no channel is running. If a new debug request is sent to the core or if a SoftBkpt is executed, it comes back to this *Debug in Sleep* state.

The OnCE is provided with several instructions that can be executed when the core is in either debug state. The following table summarizes the behavior of these OnCE debug instructions. There exists other secondary OnCE instructions that are described in [OnCE and Real-Time Debug](#).

Table 47-7. SDMA in Debug Mode

Instruction	Debug	Debug in Sleep
<code>exec_once</code>	<p><code>exec_once <instruction></code></p> <p>SDMA executes the <instruction> and returns to the <i>Debug</i> state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.</p>	<p><code>exec_once <instruction></code></p> <p>SDMA executes the <instruction> and returns to the <i>Debug in Sleep</i> state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.</p>
<code>run_core</code>	<p><code>run_core <instruction></code></p> <p>SDMA executes the <instruction>, leaves the <i>Debug</i> state and continues executing the channel script from the position where it stopped. This command must not be used with an instruction that modifies the PC value.</p>	<p><code>run_core <instruction></code></p> <p>SDMA executes the <instruction> and returns to its <i>Sleep</i> or <i>Sleep after Reset</i> initial state. This command must not be used with an instruction that modifies the PC value.</p>
<code>exec_core</code>	<p><code>exec_core <instruction></code></p> <p>It is similar to <code>run_core</code> except it requires an instruction that changes the PC value (jump, branch...): the SDMA jumps to the new PC value, leaves the <i>Debug</i> state and starts executing instructions from this new PC value.</p>	<p><code>exec_core <instruction></code></p> <p>If the previous state was <i>Sleep after Reset</i>, the SDMA returns to this state, and <code>Chn0Addr</code> value overrides the PC value.</p> <p>Otherwise, the SDMA jumps to the new PC value and starts executing instructions from this new PC.</p>

NOTE

The feature `exec_core` in *Debug in Sleep* after *Sleep after Reset* was added for the Channel boot (channel 0) to allow the debugger to return to *Sleep after Reset* state with a new PC

value. The SDMA will be ready to boot at the Chn0Addr address.

47.4.6 SDMA Clocks and Low Power Modes

The SDMA receives several root clocks from the SoC clock controller block and performs adaptive clock gating to optimize its power consumption. From a user standpoint, clock gating and power mode selection are fully automatized inside the SDMA.

Root clock control is available from the SoC clock controller block.

There are numerous clock sources that are used in the SDMA. They belong to one of two possible clock domains listed in the following table, and have frequency constraints within each domain. Clocks are considered asynchronous between domains.

Within the ARM platform/SDMA clock domain, all clocks must come from the same DPLL. The ARM platform DMA interfaces (peripheral DMA and burst DMA) receive their clock from the ARM platform DMA clock source whose frequency can be once or twice the frequency of the SDMA core clock. The DMA interfaces are designed to work at the ARM platform DMA frequency, but the SDMA core is physically limited to a maximum 104 MHz frequency. Since this is lower than the maximum ARM platform DMA frequency, the SDMA core clock is tied to the ARM platform peripheral clock frequency.

The ARM platform Peripheral Bus Clock source must be an exact sub-frequency of the SDMA Core clock source (any integer value greater or equal to 1).

Table 47-8. Clocking Scheme

Clock Domain	Source Clock	Comments
ARM platform	SDMA core (SDMA main core)	Source clock for the core and all its operations; this clock is thus used by most of the SDMA sub-blocks.
	ARM platform DMA	DMA interface for the peripheral DMA and the burst DMA. It is balanced with the main clock source, and its frequency is either once or twice the main clock frequency.
	ARM platform peripheral	Connection to the ARM platform peripheral bus. It is a sub-frequency of the main clock frequency.
JTAG	TCK	Clock for JTAG access, limited to maximum of 1/8 of the SDMA core clock frequency.

The JTAG clock is sampled by the SDMA main clock to determine its rising edge. This simplifies design and clock management, but it also adds a ratio constraint between those two clocks. It is guaranteed the JTAG interface works properly when the frequency of TCK is lower than 1/8th of the frequency of the SDMA main clock (which is about 8 MHz when the SDMA core clock frequency is 66 MHz).

47.4.6.1 Clock Gating and Low Power Modes

The SDMA automatically performs power saving without requiring user involvement. It implements two levels of automatic clock gating.

47.4.6.1.1 Coarse Clock Gating

Every sub-block clock comes from one of the five available sources, and is gated with the sub-block specific enabling condition.

The following table displays the sub-block clocks and their source. It also indicates the relationships that may exist between different sub-blocks clock enables.

Table 47-9. Sub-blocks Clocks

Sub-block	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
Core	SDMA Main Core	The core sub-block clock is running when the core is not in one of its sleep states (Sleep or Sleep after Reset) or there is a pending channel. Typically, the core sub-block clock is stopped once all the channels are processed and the core enters its sleep state. A new pending channel awakes the core sub-block clock.	None
Memories	SDMA Main Core	The clock activation only occurs during a core access.	Disabled when Core sub-block clock is disabled or no memory access in progress
Scheduler	SDMA Main Core	Its clock only runs when scheduling is needed: for example, when there are pending channels, upon reception of a DMA request, and anytime the ARM platform modifies the channel running conditions.	None
ARM platform Control	SDMA Main Core & ARM platform peripheral	The ARM platform peripheral clock is solely used to determine the frequency ratio with the SDMA main clock. The control registers' clock is based on <i>SDMA main clock</i> ; it is active when the ARM platform or the SDMA modifies the contents of one of these registers.	None
Burst DMA	SDMA Main Core & ARM platform DMA	The burst DMA has two clocks: The first clock is derived from the SDMA main core clock and drives registers that are connected to the FUBUS. The second clock is derived from the ARM platform DMA clock and drives registers that are connected to the ARM platform DMA bus outside the SDMA. Both clocks are enabled	Disabled when Core sub-block clock is disabled

Table continues on the next page...

Table 47-9. Sub-blocks Clocks (continued)

Sub-block	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
		during active phases of data transfers (for example, these clocks are turned off when the burst DMA is not used by the running channel script).	
Peripheral DMA	SDMA Main Core & ARM platform DMA	The peripheral DMA has two clocks: The first clock is derived from SDMA main clock and drives registers that are connected to the FUBUS. The second clock is derived from the ARM platform DMA clock and drives registers that are connected to the ARM platform DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the peripheral DMA is not used by the running channel script).	Disabled when Core sub-block clock is disabled
OnCE	SDMA Main Core	The OnCE clock is derived from main source clock. It is disabled by default. In order to use the OnCE, its clock must be explicitly turned on, either by enabling the OnCE access from the ARM platform peripheral bus (register ONCE_ENB), or by driving the clk_gating_off input pin high. This is a SDMA input whose driver depends on the SoC implementation (typically a JTAG controller). The OnCE also receives the TCK input, which is the JTAG clock. It does not use it as a functional clock; the TCK input is sampled instead. Refer to Synchronization Implementation .	When enabled, all other clocks are systematically on (clock gating is off)

47.4.6.1.2 Refined Clock Gating

The SDMA implements a second level of clock gating on a register-per-register basis.

Unlike the first level that covers all the SDMA flip-flops, except the synchronizers (only five flip-flops are always running), the second level is only available for eligible registers, which amounts to about 90% of the SDMA flip-flops.

These gated registers are only clocked when the hardware logic detects a new data loading. This additional gating further reduces dynamic power consumption.

47.4.6.1.3 Low Power Modes and User Control

Power savings are automatically managed by the SDMA hardware without any user involvement; however, one can distinguish three different power modes: SLEEP, RUN, and DEBUG.

The following table describes these modes, and shows how to switch from one mode to another.

Table 47-10. Power Modes

Power Mode	Sub-blocks							Comments
	Core	Mem ories	Sche duler	ARM platf orm Control	Burs t DMA	Perip heral DMA	OnC E	
SLEEP	off ¹	off	wait ²	wait	off	off	off	Set when the PCU state is either <i>Sleep</i> or <i>Sleep after Reset</i> and the SDMA is not in DEBUG mode. This is the default mode after reset.
RUN	on ³	wait	wait	wait	wait	wait	off	Set for the other PCU states that are reachable out of debug: <i>Program, Data, Change of Flow, Error in Loop, Debug, Functional Unit, Save, or Restore.</i>
DEBUG	on	on	on	on	on	on	on	Set regardless of the PCU state when clock gating is turned off to use the OnCE features (either <i>clk_gating_off</i> pin high or ONCE_ENB[0] set).

1. *off*: no clock
2. *wait*: only clocked when accessed or stimulated
3. *on*: clock is always running

It is possible to control the SDMA power mode. The procedures to force the SDMA into either mode are described in [SLEEP Mode](#).

47.4.6.1.3.1 SLEEP Mode

This is the default mode after reset; therefore, resetting the SDMA forces this mode.

However, the common procedure is as follows:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Disable all channels (via the STOP_STAT control register, and the HO, DO, EO if necessary).
- Wait for the active channels to complete or force a reschedule via the reschedule bit in the RESET register.
- The SDMA is in SLEEP mode making it possible to completely shut off its clock from the chip level clock controller using the procedure described in [Stop Mode Response](#).

47.4.6.1.3.2 RUN Mode

This is the default mode when a channel is running:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Activate at least one channel (via the HSTART control registers, a DMA request, and/or the HO, DO, EO register bits).

47.4.6.1.3.3 DEBUG Mode

The DEBUG mode must be set when one needs to use the debugging facilities of the SDMA.

- Ensure the SDMA clocks are running from the CCM.
- Set the *clk_gating_off* pin high or use the SDMA to set ONCE_ENB[0].

47.4.6.1.4 Stop Mode Response

The SDMA receives a stop request from the chip level clock controller. This request may be asserted when the chip enters the stop low power mode.

If the SDMA is running when the request is received, then the SDMA will complete all pending channels before returning to the SLEEP state. The SDMA sends an acknowledgement to the clock controller when the SLEEP state is entered indicating that the SDMA's clocks can be turned off.

47.4.6.2 Reset

After reset (either received from the reset block or a software reset required by the ARM platform), the SDMA is in IDLE mode. It will start its boot code located at address 0 once a channel is activated.

Activating a channel can be done by the ARM platform after programming a positive priority and setting the channel bit in the EVTpend register.

There will not be a context RESTORE for the first channel (bootload channel) called after a reset because the context data in RAM has not been initialized. Static context mode should be used for the first channel called after reset to ensure that all context RAM for that channel is initialized. Subsequent calls to the same channel or different channels may use any of the dynamic context modes.

47.4.7 Software Interface

Appendix A fully describes the SDMA Application Programming Interface (API).

47.4.8 Initialization Information

This section discusses the following:

- [Hardware Reset](#)
- [Channel Script Execution](#)
- [Initialization and Script Execution Setup Sequence](#)

47.4.8.1 Hardware Reset

After reset, the program RAM, context RAM, data RAM, and RAM containing the channel enable registers (CHNENBLn) have unpredictable contents.

The active register set is assigned to channel 0 and the PC is initialized to all zeros. However, since the channel enable register is all zeros, there are no active channels and the SDMA is halted waiting for the boot channel to start.

The ARM platform will have to setup the SDMA in order to boot it. The CONFIG register must be initialized to determine the DMA/core clock ratio (1 or 2). Channel Enable Registers must also be initialized.

To start up the SDMA, the ARM platform first creates some channel control blocks (CCB) and buffer descriptors (BD) in ARM platform memory for the boot channel (channel 0) and then initializes the channel 0 pointer register (SDMA_MC0PTR) to the address of the first control block. [Data Structures for Boot Code and Channel Scripts](#) provides an overview of the data structure for the CCB and BD's. The SDMA_HSTART, SDMA_HOSTOVR and SDMA_EVTOVR registers are then configured according to [Runnable Channels Evaluation](#) to allow channel 0 to run.

Upon being enabled, the SDMA begins executing the script located at the address indicated by the Channel 0 Boot Address register (SDMA_CHN0ADDR) in the program memory. The reset value of SDMA_CHN0ADDR points to the default bootload script in ROM. This ROM script will read the channel 0 pointer register (SDMA_MC0PTR) to determine the location of the Channel Control Block (SDMA_CCB) in ARM platform memory. The script will then begin fetching by DMA the first channel control block which contains a pointer to the location channel 0 Buffer Descriptor chain which is also fetched via DMA. If the buffer descriptor contains a valid command, the script interprets the command in each buffer descriptor and proceeds to implement the command and move on to the next buffer descriptor control block. The buffer descriptor commands for

channel zero are typically set up to load SDMA's program RAM, Data RAM, and initial values for the channel contexts. Some channel scripts expect particular parameters to be passed

There are two ways to make the SDMA boot on a user-defined script. The OnCE (either via its JTAG interface or its ARM platform Control interface) can be used to download any code in the SDMA RAM and force the SDMA to boot on that code. Also, the SDMA_CHN0ADDR register in the ARM platform programming model can be modified to point to user code in RAM which would need to either have been loaded via the ONCE or default bootload routine (ex before a S/W reset).

47.4.8.2 Channel Script Execution

The execution of an SDMA script depends on both the instructions that make up the script, the data context upon which it operates, and commands or parameters allowed to the buffer. All these items must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate context, but may share scripts and locations in data RAM.

Channels are initialized by the ARM platform by using channel 0 to download any required scripts and data values and the channels initial context. The context contains all the initial values of the SDMA core registers. This includes the Program Counter (PC) which is set to the start of the desired script in SDMA program memory.

The ARM platform selects which trigger conditions that must occur for the channel to start by configuring the SDMA_CHNENBL, SDMA_HOSTOVR and SDMA_EVTOVR registers. The trigger events include ARM platform setting HE (SDMA_HSTART) or a hardware DMA request asserts an event input to SDMA. The channel can become active according to its priority compared with other runnable channels when the selected trigger(s) cause the condition described in [Runnable Channels Evaluation](#) to evaluate as true.

The specific parameters to be passed to each script in the buffer descriptor or context are documented in the software documentation for each script. Please refer to [SDMA Scripts](#) for complete script documentation. [Buffer Descriptor Format](#) provides an overview of the buffer descriptor format.

47.4.8.3 Initialization and Script Execution Setup Sequence

To summarize, the following steps are minimally required to setup SDMA and run channel scripts.

- Perform Hardware Reset. The program RAM, context RAM, data RAM and SDMA_CHNENBLn registers have unpredictable contents after this reset.
- Initialize SDMA_CHNENBLn registers to map DMA request events to desired channels.
- Configure SDMA_CHNPRIn registers to select priority for runnable channels. A non-zero priority is required for the channel to run.
- Configure the SDMA_CONFIG register to select DMA to SDMA core clock ratio .
- Set up channel control blocks and buffer descriptors in ARM platform to specify the loading of SDMA program RAM and channel contexts for each SDMA channel to be used. Reference [Data Structures for Boot Code and Channel Scripts](#).
- Configure SDMA_MC0PTR register with base address of ARM platform Channel Control Block base address.
- Initialize SDMA_CHNENBLn registers to map DMA request events to associated channel. Reference [Mapping DMA Requests to Pending Channels](#).
- Configure SDMA_CHNPRIn registers to set priority for each channel to be run.
- For each channel to be run, configure SDMA_HOSTOVR (HO) and SDMA_EVTOVR (EO) registers to select which events (hardware and/or software trigger events) must occur for the channel to be runnable. Reference [Runnable Channels Evaluation](#).
- Set bit 0 of the SDMA_HSTART register to set HE[0] and allow Channel 0 to run (assumes EO[0] and DO[0] were both set in previous step). This will cause SDMA to load the program RAM and channel contexts configured previously.
- Wait for Channel 0 to finish running. This is indicated by HI[0]=1 in the SDMA_SDMA_INTR register, or by optional interrupt to the ARM platform.
- Set the LOCK bit in the SDMA_SDMA_LOCK register to prevent un-authorized uploads of data to SDMA RAM.
- Additional channel scripts can now be run by enabling the selected software or hardware trigger event according to [Runnable Channels Evaluation](#).

47.4.9 SDMA Programming Model

This section describes the programming model for the SDMA RISC engine, including its processor, memory, and internal control registers.

All addresses are related to the internal SDMA memory map, which is completely different from the ARM platform memory maps. The ARM platform processor has no access to any hardware resource described, except when those resources are described in ARM Platform Memory Map and Control Register Summary. .

47.4.9.1 State and Registers Per Channel

The SDMA can be seen as a set of 32 identical devices that are able to perform one data transfer channel each. Only one channel can work at a time, but every channel state is available at any time.

This chapter lists the components of every channel state.

47.4.9.2 General Purpose Registers

Each channel has eight general purpose registers of 32 bits for use by scripts. General register 0 has a dedicated function for the loop instruction, but otherwise can be used for any purpose.

47.4.9.3 Functional Unit State

Each channel context has some state that is part of the functional units.

The specific allocation of this state is part of the functional unit definition that is described in [Burst DMA Unit Programming](#), [Peripheral DMA Unit Programming](#).

This state must be saved/restored on context switches.

47.4.9.3.1 Program Counter Register (PC)

The PC is 14 bits. Since instructions are 16 bits in width and all memory in the SDMA is 32 bits in width, the low order bit of the PC selects which half of the 32-bit word contains the current instruction.

A low order bit of zero selects the most significant half of the word.¹

47.4.9.3.2 Flags

Each channel has the following four flags:

- The T bit reflects the status of some arithmetic and test instructions. It is set when the result of an addition or a subtraction is zero and cleared otherwise. It is also the copy of the tested bits. Finally, it can also be set when the loop counter (GReg0) reaches zero. When the last instruction of the hardware loop is an operation that can modify the T flag, its effect on T is discarded and replaced by the GReg0 status.

1. For example, big-Endian.

- Two additional bits, SF and DF, are used to indicate error conditions resulting from loading data sources and storing to destinations, respectively. Access errors set these bits, and successful transactions clear them. They can also be cleared by specific instructions (CLRF and loop). The source fault (SF) is updated by the loads LD and LDF; the destination fault (DF) is updated by the stores ST and STF.
- Access errors are caused by several conditions including writing to the ROM, writing to a read-only memory mapped register, accessing an unmapped address, or any transfer error received by a peripheral when it is accessed.

The SF and DF flags have a major impact on the behavior of the hardware loop: If SF or DF is set when starting a hardware loop and it is not masked by the loop instruction, the loop body will not be executed. Inside the loop body, if a load or store sets the corresponding SF or DF flag, the loop exits immediately. Testing the status of the T flag at the end of the loop (as well as testing both SF and DF) tells if the loop exited abnormally as any anticipated exit prevents GReg0 from reaching the zero value and thus setting the T flag. This is also valid if the fault occurs at the last instruction of the last loop.

- The last flag is the loop mode flag, LM, which is composed of two bits. The most significant bit indicates when the processor is currently operating in loop mode. It is set by the loop instruction and is cleared after execution of the last instruction of the last loop. The least significant bit is set when the program counter points to the last instruction of a loop on the last path. It is used for a channel that is restored with this configuration to know that the next program counter is EPC. As with the dynamic context switch GReg0, which indicates when the program must get out of the loop, it can be restored only on the last instruction of the loop. This, however, is too late to fetch the next instruction after the loop.

47.4.9.3.3 Return Program Counter (RPC)

The RPC is 14 bits. It is set by the jump to the subroutine instructions and used by the return from the subroutine instructions.

Instructions are available to transfer its contents to and from a general register.

47.4.9.3.4 Loop Mode Start Program Counter (SPC)

The SPC is 14 bits. It is set by the loop instruction to the location immediately following it.

47.4.9.3.5 Loop Mode End Program Counter (EPC)

The EPC is 14 bits. It is set by the loop instruction to the location of the next instruction after the loop.

47.4.9.4 Context Switching-Programming

Each channel has a separate context consisting of the eight general purpose registers and additional registers representing the state of the functional units.

The active registers and functional units contain the context of the active channel. The context of inactive channels is stored in SDMA RAM, which is part of the SDMA address space.

In a function of the selected context switching mode ([Context Switching](#)), modified registers by the program can be saved in the channel RAM space while the program is going on. In every cycle, a write access to the RAM is possible.

On a done or yield(ge) instruction, SDMA goes into "real" context switching. In one of the dynamic modes, modified registers not previously saved, as well as the PC-Loop registers, are stored into the context area of the channel that will be closed. The new PC-Loop registers are loaded from the context area of the new channel. All other registers are restored while the program is executed, giving priority to registers used by the decoded instruction. Therefore, in the best case, only the PC and Loop registers should be saved and restored during this context-switching phase, which only requires five SDMA cycles.

In static mode, the context switch stores all registers in the old channel RAM space, and restores all registers from the new channel RAM space. It requires 26 SDMA cycles.

The address of the context memory for channel i is $CONTEXT_BASE + 24*i$ or $CONTEXT_BASE + 32*i$ where $CONTEXT_BASE$ equals 0x0800. The table below presents the layout of a channel context in memory:

Table 47-11. Layout of a Channel Context in Memory for SDMA

47.4.9.5 Address Space

The SDMA has four internal buses which are listed here.

- The Instruction bus reads instructions from the memory. Its address map is described in [Instruction Memory Map](#).
- The Data bus (DMBUS) accesses the same memories as those visible on the Instruction bus, some memory-mapped registers (scheduler status and OnCE registers), and up to 14 peripherals. Its address map is described in [Data Memory Map](#).

- The Functional Units bus (FUBUS) accesses the , Burst DMA, Peripheral DMA . The addressing mechanism is further detailed in [Functional Units Programming Model](#).
- The Context Switch bus reads/writes registers into context-switch RAM space. It is a 64-bit bus dedicated for accessing this RAM space for updating the context of the running channel. While the program is going on, this bus has the lowest priority compared to the Instruction and Data buses, except for restoring a register needed for the decoded instruction to be executed. On the save part of a context switch (when the PCU is in its slave state), this is the only one used. On the restore part, the Instruction bus has the priority to read the next instruction at the restored PC and otherwise the Context Switch bus is used. It is not possible to control the actual data transfers that occur on this bus.

47.4.9.5.1 Instruction Memory Map

The instruction memory map is based on a 14-bit address bus and a 16-bit data (instruction) bus.

Instructions are fetched from either program ROM or program RAM. An SDMA script is able to change the contents of the program RAM, which is also visible from the data bus.

The first two instruction locations (at 0 and 1) are special. Location 0 is where the PC is set on reset. Location 1 is where the PC is set upon the execution of an illegal instruction. It is expected that both of these locations will contain a jmp to handle routines.

Table 47-12. SDMA Instruction Memory Space

Device	SDMA Address (Hex)	Base Address Label	Block Name	WS	Description
ROM	0x0000 ↓ 0x07FF	SDMA_IBUS_ROM_ADDR	-	0	4 Kbyte internal ROM with boot code and standard routines.
RAM	0x1000 ↓ 0x1FFF	SDMA_IBUS_RAM_ADDR	-	0	8 Kbyte internal RAM with channels context and user data/routines.

47.4.9.5.2 Data Memory Map

All of the data accessible to SDMA scripts make up the data memory space of the SDMA.

This address space has several components:

- ROM (also visible on the Instruction bus)
- RAM (also visible on the Instruction bus)

Functional Description

- Shared Peripherals Registers
- SDMA Internal Registers (scheduler, OnCE, and registers that are also accessible by the ARM platform)

SDMA scripts can read and write to the context RAM, data RAM, shared peripheral registers, and internal registers.

The address range is 16 bits and the data width is 32 bits. When accessing peripheral registers (USB and so on), the data width may be different. The exact address map for the peripherals depends on the project (as presented in each respective chapter).

Data access is performed with *ld* and *st* instructions that take the address from a general purpose register in the core (GRegn). The mapping between the general purpose register contents and the address bus is given in the following table:

Table 47-13. GRegn to DMBUS Address Mapping

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sz	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
address															

Grayed bits are simply discarded but they must be cleared to ensure forward-script compatibility.

- sz (bit 31) indicates the peripheral data width: 0 is used for a 32-bit peripheral and 1 is used for a 16-bit peripheral.
- address (bits 15 down to 0) is the address of the accessed resource (internal memory, internal register, or shared peripheral).

Table 47-14. SDMA Data Memory Space

Device	SDMA Address (Hex)	Size	Description
ROM	0x0000 → 0x03FF	4 Kbyte	4 Kbyte internal ROM with boot code and standard routines
Reserved	0x0400 → 0x07FF	4 Kbyte	4 Kbyte Reserved

47.4.10 SDMA Initialization

Appendix A describes the setup of the SDMA . This section provides a quick description of several initialization procedures.

NOTE

There may be differences with the actual implementation in the API.

47.4.10.1 Hardware Reset-SDMA

After reset, the RAM that holds contexts, data, scripts, and the DMA request-channels matrix has unpredictable content.

The core registers are all reset to 0, including the PC; the PCU state is *Sleep after Reset*. No channel can be activated because all of the priorities are also reset to 0.

47.4.10.2 Standard Boot Sequence

The following is the standard boot sequence:

1. Initialize the CONFIG register-detailed in [Configuration Register \(SDMAARM_CONFIG\)](#)-to determine the ARM platform DMA/core clock ratio (1 or 2)
2. Initialize the DMA request-channels matrix (see [Channel Enable RAM \(SDMAARM_CHNENBL_n\)](#)).
3. Program the channel control registers-[Channel Event Override \(SDMAARM_EVTQVR\)](#), [Channel BP Override \(SDMAARM_DSPOVR\)](#), Channel

BP Override (SDMA_HOSTOVR), and [Channel Event Pending \(SDMAARM_EVTPEND\)](#)-according to the channel allocation.

4. Perform any necessary setup as required by the standard boot script in ROM (this is described in Appendix A).
5. Trigger channel 0 with the [Channel Start \(SDMAARM_HSTART\)](#) register, which starts the execution of the ROM script starting at address 0. This boot downloads channel scripts and contexts in RAM.

47.4.10.3 User-Defined Boot Sequence

The following is a user-defined boot sequence:

1. Initialize the [Configuration Register \(SDMAARM_CONFIG\)](#)[Channel Enable RAM \(SDMAARM_CHNENBL \$n\$ \)](#), [Channel Event Override \(SDMAARM_EVTOVR\)](#), [Channel BP Override \(SDMAARM_DSPOVR\)](#), [Channel ARM platform Override \(SDMAARM_HOSTOVR\)](#), and [Channel Event Pending \(SDMAARM_EVTPEND\)](#).
2. Use the OnCE (either via its JTAG interface or its ARM platform control registers) to download any code in the SDMA RAM. [Accessing the Memory](#) describes how to write data to the RAM via the OnCE.
3. Use the OnCE instructions to make the PC default value point to the new boot script start address, or rely on the ROM startup script, which first jumps to the address in [Channel 0 Boot Address \(SDMAARM_CHN0ADDR\)](#). (This register default address points to the standard boot script.)

47.4.10.4 Script Loading and Context Initialization

The execution of an SDMA script depends on both the instructions that make up the script and the data context upon which it operates. Both must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate data context, but may share scripts and locations in the data RAM.

The ARM platform manages the space in program RAM and data RAM. It also manages the assignment of SDMA channels to the device drivers that need them. Channels are initialized by the ARM platform via the channel 0 boot script. The boot channel downloads any required scripts with their data and the channels' initial contexts. Every context contains all the initial values of the registers, including the PC. Then the ARM platform can enable any channel that becomes active and begins fetching and executing instructions from its script.

47.4.11 Instruction Description

The following sections introduce the instruction of the SDMA.

Instruction set details are available in [Instruction Set](#).

47.4.11.1 Scheduling Instructions

The following are scheduling instructions:

- **done**-The instruction causes certain scheduling or interrupt bits to be set or cleared, which may cause a change in the schedule-ability of the running channel. Then the instruction causes the SDMA to evaluate the current scheduling priorities and to choose the highest priority ready channel. If this channel is not the current channel, a context switch will take place. If there are no runnable channels, the SDMA will enter the stopped mode. The done 5 has a special usage reserved for debug, as explained in [Debug Instructions](#).
- **yield**-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater than the current channel priority.
- **yieldge**-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater or equal to the current channel priority.
- **notify**-The notify instruction affects the scheduling bits, but does not cause rescheduling.

47.4.11.2 Conditional Branch Instructions

The conditional branch instructions of an 8-bit displacement, which is sign-extended and added to the current PC (which points to the next instruction) if the condition is satisfied.

Otherwise, control passes to the next sequential instruction.

- **BF**-Branch if False. The branch is taken if the T bit in the processor status is zero (false).
- **BT**-Branch if True. The branch is taken if the T bit in the processor status is one (true).

- **BSF-Branch if Source Fault.** The branch is taken if the SF bit in the processor status is one.
- **BDF-Branch if Destination Fault.** The branch is taken if the DF bit in the processor status is one.

47.4.11.3 Unconditional Jump Instructions

There are two varieties of unconditional control transfers: an absolute transfer and a through-register transfer.

Absolute transfers have a 14-bit address field that replaces the current PC.

- **JMP-Jump.** Causes the processor to jump to an absolute address encoded in the instruction itself.
- **JSR-Jump to Subroutine.** Causes the processor to jump to a subroutine, the address of which is encoded in the instruction itself.
- **JMPR-Jump through Register.** Causes the processor to jump to an absolute address contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.
- **JSRR-Jump to Subroutine through Register.** Causes the processor to jump to a subroutine, the address of which is contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.

47.4.11.4 Subroutine Return Instructions

The following are subroutine return instructions:

- **RET-Return from Subroutine.** The RET restores the contents of RPC to PC.
- **LDRPC-Load from RPC to Register.** THE LDRPC instruction is meant to be used when more than one level of subroutines are required. It stores the contents of RPC in any General register.

47.4.11.5 Loop Instruction

The following is a loop instruction:

LOOP-Enters Loop Mode. Before entering loop mode, the loop instruction can optionally clear the fault flags (SF and/or DF) based on a 2-bit field in the instruction. This feature is linked to the fact that setting SF or DF in loop mode will cause an immediate exit of the loop.

47.4.11.6 Miscellaneous Instructions

The following are miscellaneous instructions:

- CLRF-Clear Fault Flags. This instruction clears any combination of SF and DF.
- MOV r,s-This moves data from GReg[s] to GReg[r].
- LDI r,immediate-This loads GReg[r] with a zero-extended immediate value.

47.4.11.7 Logic Instructions

The following are logic instructions:

- XORr,s-This performs an exclusive or between GReg[r] and GReg[s], and stores the result in GReg[r].
- XORIr,immediate-This performs an exclusive or between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- ORr,s-This performs an or between GReg[r] and GReg[s], and stores the result in GReg[r].
- ORIr,immediate-This performs an or between GReg[r] and a zero-extended immediate value and, stores the result in GReg[r].
- ANDNr,s-This performs an and between GReg[r] and the negated GReg[s], and stores the result in GReg[r].
- ANDNIr,immediate-This performs an and between GReg[r] and the negated zero-extended immediate value, and stores the result in GReg[r].
- ANDr,s-This performs an and between GReg[r] and GReg[s], and stores the result in GReg[r].
- ANDIr,immediate-This performs an and between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].

47.4.11.8 Arithmetic Instructions

Arithmetic instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the result is zero, otherwise it is cleared.

- ADD r,s-This performs the addition of GReg[r] and GReg[s], and stores the result in GReg[r].
- ADDI r,immediate-This performs the addition of GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].

- SUB r,s-This performs the subtraction of GReg[s] from GReg[r], and stores the result in GReg[r].
- SUBIr,immediate-This performs the subtraction of a zero-extended immediate value from GReg[r], and stores the result in GReg[r].

47.4.11.9 Compare Instructions

Compare instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the comparison is true, otherwise it is cleared.

NOTE

Only one version of the immediate form is implemented. Non-equality comparisons to immediate values will require two instructions.

- CMPEQ r,s-This sets T when registers GReg[r] and GReg[s] are equal.
- CMPEQIr,immediate-This sets T when register GReg[r] and the zero-extended immediate value are equal.
- CMPLTr,s-This sets T when register GReg[r] is less than and not equal to GReg[s]. The comparison is signed.
- CMPHS r,s-This sets T when register GReg[r] is greater than or equal to GReg[s]. The comparison is signed.

47.4.11.10 Test Instructions

Test instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if any bit in the result is one, otherwise it is cleared.

- TSTr,s-This performs an and between GReg[r] and GReg[s], and sets T if the result is not zero.
- TSTIr,immediate-This performs an and between GReg[r] and a zero-extended immediate value, and sets T if the result is not zero.

47.4.11.11 Byte Permutation Instructions

These instructions shuffle the bytes in a register. For the purpose of describing these instructions, have the bytes in a register be numbered from the most significant as b_3 , b_2 , b_1 , b_0 .

- RORBr-The rotate right byte. The result is b_0 , b_3 , b_2 , b_1 .

- REVB_r-The reverse bytes in word. The result is b_0, b_1, b_2, b_3 .
- REVBL_{Or}-The reverse, two low-order bytes. The result is b_3, b_2, b_0, b_1 .

47.4.11.12 Bit Shift Instructions

The following are bit shift instructions:

- ROR1_r-The rotate right 1 bit. This instruction does a circular right shift of 1 bit.
- LSR1_r-The logical shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by a 0.
- ASR1_r-The arithmetic shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by itself.
- LSL1_r-The logical shift left 1 bit. This instruction shifts all bits to the left by 1. The low order bit is replaced by zero.

47.4.11.13 Bit Manipulation Instructions

- BCLR_{r,n}-The bit clear is immediate; clears bit number i in register r .
- BSET_{r,n}-The bit set is immediate; sets bit number i in register r .
- BTST_{r,n}-The bit test is immediate; tests bit number i in register r (T becomes equal to the selected register bit).

47.4.11.14 SDMA Memory Access Instructions

All memory accesses are 32 bits.

Any memory location that is implemented with less than 32 bits (for example, peripheral registers) causes unimplemented bits to be read as 0s.

All memory accesses will cause either the SF or DF flags in the processor status to be set if they cause a fault.

What constitutes a fault, especially when accessing peripheral registers, is a property of the memory location.

- LDr,(b,d)-The load instruction creates an address by adding the displacement field (d) to the contents of the base register (b). The SDMA location at the resulting address is read and placed in the destination register (r).
- ST_r,(b,d)-The store instruction creates an address in the same manner as the load instruction. The register (r) is stored in the SDMA location at the resulting address.

47.4.11.15 Functional Unit Instructions

The functional unit instructions have an 8-bit field that is placed on the functional unit bus.

Some of these bits are used to select which functional unit should be involved in the transfer. The remaining bits are decoded by the selected functional unit so their specific use depends on the functional unit. See [Functional Units Programming Model](#).

There are two functional unit instructions, as follows:

- LDFr,fub-The 8-bit field is placed on the functional unit bus and a read is issued to the selected functional unit. As a result of this instruction, the SF may be set in the processor status.
- STFr,fub-The 8-bit field is placed on the functional unit bus and a write is issued to the selected functional unit. As a result of this instruction, the DF may be set in the processor status.

47.4.11.16 Illegal Instructions

All instruction encodings that are illegal cause the following actions:

- The current PC (which points to one beyond the offending instruction) is put in the EPC register.
- The loop mode bit is cleared.
- The PC is set to the value stored in the [Illegal Instruction Trap Address \(SDMAARM_ILLINSTADDR\)](#) register (the default value is 0x0001).

ILLEGAL-Although any instruction other than those indicated in the SDMA specification will trigger the illegal instruction mechanism, the ILLEGAL instruction code is preferred as it will always be kept as *illegal* in the possible future versions of the SDMA core.

47.4.11.17 Debug Instructions

The following are debug instructions:

- SOFTBKPT-The software breakpoint instruction causes the core to stop and enter debug mode. The core can then be accessed and started by the OnCE debug block only.

- done 5-This instruction is used for debugging, as it copies the contents of the PCU registers and flags to the context memory. Information on this instruction is described in [Saving the Context](#).
- CpShReg-This instruction copies the context memory into the PCU registers and flags. Modifying the corresponding memory location before executing this instruction enables you to have the channel continue from a new instruction address. This instruction is described in [Restoring the Context](#).

47.4.12 Functional Units Programming Model

The functional unit instructions cause an 8-bit code, found in the low eight bits of the instruction, to be asserted on the functional unit control bus.

Some of these bits are used to select one of several functional units. Functional units which can be selected include SDMA registers such as MSA and MSD which are not mapped in the SDMA memory map, and are accessible only through the functional unit bus. These Functional Unit Registers are listed in the following table. In order to establish a programming convention, assume the selection bits are some number of the most significant bits of the 8-bit code. Furthermore, some number of the least significant bits is decoded by a given functional unit to establish the type of operation to perform.

Table 47-15. Functional Unit Registers

Functional Unit	Register	Register Name	Section/Page
Burst DMA Unit Programming	SDMSA	Memory Source Address Register	Memory Source Address Register (MSA)
	MDA	Memory Destination Address Register	Memory Destination Address Register (MDA)
	MD	Memory Data Buffer Register	Memory Data Buffer Register (MD) (Write) Burst DMA Write (stf) (Read) Burst DMA Read (Idf)
	MS	Memory State Register	State Register (MS)
Peripheral DMA Unit Programming	PSA	Peripheral Source Address Register	Peripheral Source Address Register (PSA)
	PDA	Peripheral Destination Address Register	Peripheral Destination Address Register (PDA)
	PD	Peripheral Data Buffer Register	Peripheral Data Register (PD) (Write) Peripheral DMA Write (stf)-Write Mode

Table continues on the next page...

Table 47-15. Functional Unit Registers (continued)

Functional Unit	Register	Register Name	Section/Page
			(Read) Peripheral DMA Read (ldf)-Read Mode
	PS	Peripheral State Register	Peripheral State Register (PS)

More information regarding the functional units can be found in [Peripheral DMA Unit](#), and [Burst DMA Unit](#).

47.4.12.1 Burst DMA Unit Programming

The DMA instructions control the DMA state machine and may cause a DMA cycle on the associated memory bus.

There are four registers associated with the burst DMA unit: a Memory Source Address register (MSA), a Memory Destination Address register (MDA), a Memory Data buffer (MD), and a state register (MS). The burst DMA has two different uses:

- A data transfer between External Memory Interface and SDMA general register
- A data transfer in copy mode where blocks of data are transferred from the source address to the destination address

47.4.12.1.1 Memory Source Address Register (MSA)

The source address register contains the pointer into EXTMC memory associated with the next read data transfer. It has byte granularity.

Reading the register with the ldf instruction has no side effects, and gives the address value in the EXTMC memory of the next data that is read by the SDMA during an ldf MD instruction.

Writing the source address register has two side effects: If the prefetch bit is set, a DMA read cycle (8-word read access) is issued with the new address. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MSA to guarantee all the data is effectively written to memory.

The MSA register has two modes of programming:

- Frozen-In frozen mode, the MSA register is not modified after DMA accesses.
- Incremented (default mode)-In incremental mode, MSA is incremented by the number of bytes transferred during read cycles.

47.4.12.1.2 Memory Destination Address Register (MDA)

The destination address register contains the pointer into EXTMC memory associated with the next write data transfer. It has byte granularity.

Reading the MDA register with the `ldf` instruction has no side effects. It gives the address value in the EXTMC memory where the next SDMA data (`stf r,MD` instruction) is stored when MD FIFO is flushed.

Writing the destination address register has one side effect. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MDA to guarantee all the data is effectively written to memory.

The MDA register has two modes of programming:

- Frozen-In frozen mode, the MDA register is not modified after DMA accesses.
- Incremented (default mode)-The MDA register is incremented by the number of bytes transferred during write cycles.

47.4.12.1.3 Memory Data Buffer Register (MD)

The data buffer register consists of a bank of 36 bytes that behave like FIFO.

This FIFO stores the eight words received when a read burst is triggered by the DMA (DMA is in read mode).

The MD register is in write mode after a writing in MDA or after an `stf MD` instruction.

In that case, a burst write access is automatically triggered when there are more than eight words in MD. For bandwidth optimization, any transfers between DMA and the EXTMC controller are based on burst accesses.

An `ldf r,MD|SIZE` instruction that reads the data buffer may cause a DMA cycle, as follows:

- If there are less bytes in the FIFO than the size parameter of the instruction. For instance, if only two bytes are available in MD and a 4-byte read is requested, a burst read access is executed to complete the two bytes.
- If the prefetch bit is set, and after reading there is enough space in the FIFO to store a full burst, a burst read access is triggered.

An `stf r,MD|SIZE` instruction that writes to the data buffer may cause a DMA cycle if the number of written bytes in MD is higher than 32 (eight words) or if the flush bit is set.

Functional Description

When DMA is used for data transfer between SDMA and EXTMC (reading or writing), no immediate error is possible because the block manages a data misalignment issue; therefore, it is allowed to read/write a word to/from a half-word address. However, the addresses (source or destination) must belong to the EXTMC memory mapping. The only potential error, in this mode, would be the error sent back by the EXTMC controller when an access to a super-user page is detected. The whole transfer on the DMA associated bus will be considered successful when there are no errors seen on the bus during the transfer. In copy mode, an immediate error could be returned to SDMA as described in [Burst DMA Unit Error Management](#).

47.4.12.1.4 State Register (MS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer. MS is also accessed to set-up the conditional yielding feature.

The initialization value of this register is 0 and it consists of the following:

Table 47-16. SDMA_MS Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																

Table 47-17. SDMA_MS Field Descriptions

Field	Description
31-22	Reserved
21 spriv	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
20 stype	Source Mode. Indicates if MSA has to be incremented (or not) during accesses. 0 Frozen-MSA is not modified. 1 Incremented-MSA is incremented by the number of transferred bytes during read access.
19-18	Reserved
17 dpriv	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved
16	Destination Mode. Indicates if MDA has to be incremented (or not) during accesses.

Table continues on the next page...

**Table 47-17. SDMA_MS Field Descriptions
(continued)**

Field	Description
dtype	0 Frozen-MDA is not modified. 1 Incremented-MDA is incremented by the number of transferred bytes during write access.
15-12	Reserved
11 y	Conditional Yielding selector. When selected, theyield/yieldge instructions will not switch channels if the Burst DMA is in Write Mode, and it has less than four bytes in its FIFO. This is aimed at reducing the number of inefficient FIFO flushes due to context switches. 0 Always yields 1 Yields conditionally (when there are less than four bytes in the FIFO in write mode)
10 d	Access Direction or DMA Mode. DMA is in write mode when data was written into MD by stf MD instructions, or if a previous DMA cycle on the external bus was a write access. Writing MDA or MSA changes the DMA mode to the respective value. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by SDMA with an ldf MD instruction. Reading MDA or MSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 <i>reserved</i> 10 Error mode 11 error read burst
7-6	Reserved
5-0 n	Number of bytes in the MD FIFO.

47.4.12.1.5 Burst DMA Write (stf)

When received from a stf instruction, the function code bits are interpreted as follows, depending on the addressed register:

Table 47-18. STF Code Bits

Register	7	6	5	4	3	2	1	0
MSA	s		p	freeze	r			spriv
MDA								dpriv
MD			f	cpy				sz
MS								

Table 47-19. STF Code Bit Field Descriptions

Field	Description
7-6 s	Functional Unit selector 00 for Burst DMA
5 p (MSA)	Prefetch Flag 0 No prefetch 1 Prefetch required from new MSA
5 f (MD)	Forced Flush Flag 0 Automatic flush 1 FIFO contents are flushed (including the new written data).
4 freeze (MSA/MDA)	Address Freeze Mode 0 Address is normally incremented. 1 Address is frozen.
4 cpy (MD)	Copy Mode selection 0 Write Mode 1 Copy Mode
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD/MS)	Transfer Size 00 size 0 (no data stored in the FIFO) 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
0 spriv (MSA)	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
0 dpriv (MDA)	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved

The possible write instructions are listed in the table below (unused bits should always be cleared).

Table 47-20. Burst DMA STF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	stf r,MSA	Writes content of the SDMA general register (r) to the source address register. MSA is in incremented mode.

Table continues on the next page...

**Table 47-20. Burst DMA STF Instruction List
(continued)**

Binary	Assembly	Comments
00_0_1_00_00	stf r,MSAIFR	Writes content of the SDMA general register (r) to the source address register. MSA is in frozen mode.
00_1_0_00_00	stf r,MSAIPF	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access. MSA is in incremented mode.
00_1_1_00_00	stf r,MSAIPFIFR	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access.
00_0_0_01_00	stf r,MDA	Writes content of the SDMA general register (r) to the destination address register. MDA is in incremented mode.
00_0_1_01_00	stf r,MDAIFR	Writes content of the SDMA general register (r) to the destination address register. MDA is in frozen mode.
00_1_0_10_00	stf r,MDISZ0IFL	No data transfers between the SDMA and MD, but all valid written data of the MD is flushed to the memory. An acknowledge or error is sent back to the SDMA core on transfer completion.
00_0_0_10_01	stf r,MDISZ8	8-bit (byte) transfer to write buffer MD
00_1_0_10_01	stf r,MDISZ8IFL	8-bit (byte) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_10	stf r,MDISZ16	16-bit (half-word) transfer to write buffer MD
00_1_0_10_10	stf r,MDISZ16IFL	16-bit (half-word) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_11	stf r,MDISZ32	32-bit (word) transfer to write buffer MD
00_1_0_10_11	stf r,MDISZ32IFL	32-bit (word) transfer to write buffer MD and flush after transfer. All valid written data of MD is flushed to memory.
00_0_1_10_00	stf r,MDICPY	No data transfer between SDMA and MD but starts a copy transfer whose length is given by the 4 LSB of r register. (Maximum burst length is eight words.)
00_0_0_11_11	stf r,MS	32-bit (word) transfer to status register MS
00_0_0_11_00	stf r,MSISZ0	Clears the error flag (if set). Other MS bits are unchanged; this instruction is also known as clref MS.

NOTE

When a flush bit is set, the SDMA flushes the FIFO including the newly written data. An acknowledge is sent to the core before the flush completes (except if size 0 is used). The goal of this flush bit is to force a flush, but it is recommended to use it only when needed (for example, when finishing a row of pixels during 2D data transfers). Indeed, if this bit is omitted and if there are more than 32 bytes in the FIFO, a burst write access is automatically triggered.

Since all the stf r,MD instructions (including the copy mode) acknowledge the SDMA core before the store is effective (except if size 0 is used), it is recommended to perform an ldf

Functional Description

from MS before terminating a channel in order to check the final error status. (The ldf from MS will stall the core until all the data was flushed out and the transfer status is known.)

After every stf MD instruction, the MDA is incremented by the number of bytes that are written in MD, except when it is programmed in frozen mode.

47.4.12.1.6 Burst DMA Read (ldf)

When received from an ldf instruction, the function code bits are interpreted as follows, depending on the addressed register:

Table 47-21. LDF Code Bits

Register	7	6	5	4	3	2	1	0
MSA	s				r			
MDA								
MD		p					sz	
MS								

Table 47-22. LDF Code Bit Field Descriptions

Field	Description
7-6 s	Functional Unit selector 00 for Burst DMA
5 p (MD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD)	Transfer Size 00 reserved 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

The table below lists the possible write instructions (unused bits should always be cleared).

Table 47-23. Burst DMA LDF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	ldf r,MSA	Copies the source address register value into an SDMA general register. It gives the memory address of the next data that will be read with an ldf MD instruction.
00_0_0_01_00	ldf r,MDA	Copies the destination address register value into an SDMA general register. It gives the memory address where the next incoming data will be flushed.
00_0_0_10_01	ldf r,MDISZ8	8-bit (byte) read
00_1_0_10_01	ldf r,MDISZ8IPF	8-bit (byte) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_10	ldf r,MDISZ16	16-bit (half-word) read
00_1_0_10_10	ldf r,MDISZ16IPF	16-bit (half-word) read. If after this reading, and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_11	ldf r,MDISZ32	32-bit (word) read
00_1_0_10_11	ldf r,MDISZ32IPF	32-bit (word) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_11_00	ldf r,MS	Copy the status register value into an SDMA general register.

NOTE

Read data is 0-extended before writing in the SDMA general registers. When reading the MD register, the DMA takes data from the FIFO if it is available. If part or whole data is not in the FIFO, an external burst read access is performed to provide the missing data. The SDMA is stalled as long as the required read data is not complete.

After every reading, MSA is incremented by the number of read bytes from MD FIFO, except when MSA is programmed in frozen mode.

47.4.12.1.7 Prefetch/Flush and Auto-Flush Management-Burst DMA Unit

The prefetch and auto-flush management enables the SDMA RISC machine to go on while a DMA access is performed.

When the RISC core requires a prefetch ($p = 1$) to the Burst DMA, it will receive an immediate transfer acknowledge before the DMA has finished the external access. This enables the RISC core to do other things like accessing another DMA machine.

The basic principle in prefetch mode is for the DMA to anticipate data reads from the SDMA RISC engine by fetching external bursts of data as soon as there is enough space in the DMA FIFO to store it. If ever the RISC engine required data that is not available in the FIFO, the read acknowledge is delayed until the data is available, but it does not have to wait until the burst completes.

The auto-flush basic principle is similar: An automatic flush is triggered every time there are eight words to be written in the FIFO. If the FIFO is full and the RISC engine requires another write, it is stalled until the burst has started and enough space was freed in the FIFO to store that new data. This means the SDMA RISC engine does not have to wait for the completion of a burst to receive its acknowledge and continue its processing.

In particular, an auto-flush is executed when DMA is in write mode and if the following is true:

- If the FIFO is empty and the first write is to a word-aligned address of any size (ex: the 2 LSB of MDA[1:0]= 0x0), the auto-flush is triggered immediately after the write of the 32'nd byte.
- If the FIFO is empty, and if MDA is an odd byte address (1, 3, 5, 7,...) and an stf MDISZ8 is executed, the byte is flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is a half-word address (2, 6, 0xA,...) and an stf MDISZ16 is executed, the two bytes of the incoming data are flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is not a word-aligned address (ex 1, 2, 3, 5, 6, 7, 9,...), and an stf MDISZ32 is executed, the first 1 to 3 bytes will be flushed up to the next word aligned address. Afterwards, an auto-flush will be triggered each time the FIFO receives 32-bytes.
- Therefore, if an stf MDISZ32 is executed with MDA equal to 0x1 and with an empty MD FIFO, the bytes located at addresses 1, 2, and 3 are flushed, and the byte located at address 4 remains in MD FIFO. This solves the misalignment issue. Additionally, the next write instructions (stf) complete the FIFO until it contains eight words; then a burst write is executed by the DMA to empty the FIFO. Protocol on the external bus does not support bursts of different data types (byte, half-word, or word).

For example, consider the case where data is written using a byte access, stf MDISZ8. The value of MDA during the very first byte write determines when the auto-flush will occur as follows:

- If MDA=0x0, the flush occurs following the write of byte 32
- If MDA=0x1, the flush occurs following the write of byte 1, byte 3 and byte 35.
- If MDA=0x2, the flush occurs following the write of byte 2 and byte 34.

- If MDA=0x3, the flush occurs following the write of byte 1 and byte 33.
- If MDA=0x4, the flush occurs following the write of byte 32

The flush command forces the DMA to flush all MD valid bytes to the EXTMC controller. An acknowledge is sent immediately to the SDMA, and any potential error is reported on a future access. It is thus essential to conclude a transfer with a last read from MS, which will stall the core until all data was flushed out and returned to the transfer status (acknowledge or error).

NOTE

During this kind of auto-flush (which occurs only at the beginning of a misaligned write transfer) no acknowledge is sent back to the SDMA, which is stalled until a flush is completed.

47.4.12.1.8 Data Alignment and Endianness-Burst DMA Unit

47.4.12.1.8.1 Burst DMA in Read Mode

For every read access to MD, the data returned to the SDMA core and the new FIFO state depends on the MSA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is fetched externally on a 32-bit bus, but the valid bytes only are stored in the FIFO and left-aligned (for a transfer of consecutive words, it is only the first word that may be truncated). The following table shows the FIFO byte alignment strategy and the corresponding MSA, the returned data, and the new FIFO state for any access size of an internal read from MD.

Table 47-24. FIFO Read Configuration

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
00	x0 x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 and so on...	sz8	00 00 00 x0	01	x1 x2 x3 y0 y1 y2 y3 z0
		sz16	00 00 x0 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz32	x0 x1 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
01	x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 and so on...	sz8	00 00 00 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz16	00 00 x1 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz32	x1 x2 x3 y0	01	y1 y2 y3 z0

Table continues on the next page...

Table 47-24. FIFO Read Configuration (continued)

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
					z1 z2 z3 t0
10	x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 and so on...	sz8	00 00 00 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz16	00 00 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz32	x2 x3 y0 y1	10	y2 y3 z0 z1 z2 z3 t0 t1
11	x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 t2 and so on...	sz8	00 00 00 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz16	00 00 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
		sz32	x3 y0 y1 y2	11	y3 z0 z1 z2 z3 t0 t1 t2

47.4.12.1.8.2 Burst DMA in Write Mode

For every write access to the MD, the new FIFO state depends on the MDA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is stored in the FIFO according to the internal access size and the former MDA value. The following table shows the FIFO byte alignment strategy corresponding to MDA, as well as the new FIFO state for any access size of an internal write to MD.

Table 47-25. FIFO Write Configuration

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
00	tt uu vv ww ?? ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	01	tt uu vv ww x0 ?? ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	10	tt uu vv ww x0 x1 ?? ?? ?? ?? ?? ??

		sz32	x0 x1 x2 x3	11	tt uu vv ww xx yy zz x0 x1 x2 x3 ??

NOTE

If the FIFO mode changes from a write to a read mode, all remaining written bytes in MD are lost but no error is returned. Typically, this happens if an ldf MD is executed after stf MD instructions. Before a mode change, it is recommended to force the flush of a potential remaining byte by a stfMD|SZ0|FL instruction. In the same way, if a FIFO mode changes from a read to a write mode, all prefetched data present in the FIFO is lost and no error is returned.

47.4.12.1.8.3 Endianness-Burst DMA Unit

Big and Little Endian are supported by the Burst DMA, but data is always stored in MD in Big Endian.

Byte manipulation is performed when data is exchanged with an Burst controller (for example, during read or write burst accesses).

47.4.12.1.9 Burst DMA Unit Copy Mode

A mechanism is available to perform fast ARM-to-ARM transfers.

Data does not flow through the SDMA core: It is kept in the DMA FIFO. This mechanism is selected when writing MD with a special option in the instruction code (copy flag).

It is possible to transfer up to eight words in one SDMA instruction (this does not mean in one cycle). In this mode, every time an stf MDICPY is executed, a read burst is executed and directly followed by a write burst transfer. Burst transfers are limited to eight words. The size of the transfer (in words)-given by the SDMA general register (4 LSB)-is also limited to eight. The following SDMA code shows how 100 bytes could be copied from the MSA address to the MDA address. This is sample code only.

Burst DMA copy mode example

```

ldi r0,@src
stf r0,MSA // Source address setup
ldi r1,@dst
stf r1,MSA // Destination address setup
ldi r0,0x64 // data transfer counter
ldi r1,0x8

MAIN_XFER:
cmphs r0,r1 // Is r0 >= 0x8
bf LAST_XFER // If not, jump to last transfer label
stf r1,MD|CPY // Copy 8 words from MSA to MDA address.
subi r0,0x8 // Decrement counter
jmp MAIN_XFER // return to main transfer loop

LAST_XFER:
stf r0,MD|CPY

```

The main transfer loop is executed 12 times; then r0 equals 4 and the last transfer loop is run.

In this mode, an acknowledge is transmitted to the core as soon as the read burst can start; thus, a first copy instruction returns an immediate acknowledge and subsequent copy instructions will be acknowledged as soon as the previous copy has finished.

47.4.12.1.10 Burst DMA Unit Error Management

Another point to consider is the management of errors.

Because the DMA immediately sends an acknowledge to the RISC core (except for the stf MS|SZO|FLS instruction), it assumes no error will occur. If an error occurs, it is flagged (transfer error acknowledge) for the following DMA access.

This should not be a problem if the DMA is used properly. The MD accesses are meant to stall the SDMA as little as possible to optimize throughput and hide calculation time. Therefore, final access to MS should be performed before closing a channel. This access waits until any pending operation is finished in the burst DMA and gather any remaining error.

In copy mode, an error could be immediately returned to the SDMA on execution of the ldf copy or stf copy instruction. It happens when MSA or MDA are not word addresses (for example, 0[4]). This is because copy mode must only be used for transferring a large packet of aligned data.

When an error is received during a *read* transfer to the external bus, which may occur during the burst accesses, the MD FIFO contains the valid beats of the burst, and the error flag of MS is set to 2'b11 (error read burst). It is possible to read MS ("n" field) to know how much valid data remains in MD and when MD is empty (after ldf instructions). The next read MD instruction sets the MS error flag to 2'b10 (error mode), and an error is sent back to the SDMA core. In error mode, it is possible to read MSA, which gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, gives rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

In "error read burst" mode, writing MDA, MSA, or MD, or starting a copy transfer by a stf MDICOPY instruction will cancel the error mode. The following table shows when an immediate error is sent back according to the executed instruction.

Table 47-26. Possibilities in ERROR READ BURST Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA (IU IPF) stf rn, MDA stf rn, MDICOPY	NO	Error mode is reset. MSA, MDA, or MD are updated and a DMA cycle may start. For the stf MDICOPY, a copy loop is executed.
stf rn, MS	NO	MS is updated.

Table continues on the next page...

Table 47-26. Possibilities in ERROR READ BURST Mode (continued)

DMA Instruction	Immediate Error	Comments
ldf rn, MS ldf rn, MSA ldf rn, MDA	NO	MS, MSA, and MDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	YES/NO	Immediate error if there is no more data available for read in the FIFO.

When an error is received during a *write* transfer, the error is reported to the next DMA access. In this case, an error is sent to the SDMA core and the DMA goes to its error mode. Reading MS gives the number of bytes that remain in MD; reading MDA gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, give rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

Table 47-27. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA stf rn, MDA	Yes	Any attempt to modify MD, MSA, MDA will raise an immediate error and burst DMA remains in error mode. When address registers are write-accessed, an error is returned.
stf rn, MS	No	This is the only way to exit error mode. MS[9:8] must be reset by an stf MSISZ0 instruction.
ldf rn, MS ldf rn, MSA ldf rn, MDA	No	MS, MSA, and MDA could be read in error mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	Yes	Whatever the DMA direction (read or write), an ldf rn triggers an immediate error.

47.4.12.1.11 Conditional Yielding-Burst DMA Unit

The standard SDMA transfer is based upon a hardware loop that has the following structure:

Hardware Loop

```

loop
load Rn,source           // can be ldf or ld
<computation>           // can be done through functional units
store Rn,dest            // can be st or stf
done 0                   // yield

```

This structure needs to be kept independent of the functional units' particularities regarding the context switch. However, there can be variations in the context switch's efficiency, which can depend on the number of data received up to that point, and on the data itself.

The DMA, with its 8-word burst capability, has a preferable context switch period when its address register is 8-word aligned: It is the only moment that occurs once every eight loops when the succession of bursts is not broken by the context switch. When this is not the case, a context switch requires the storing (or loading) of less than eight words, which requires separate accesses and is far less efficient. The rest of the 8-word packet is stored (or loaded) after the context restore, and this is done as separate accesses.

The proposed solution is a conditional yielding, which occurs only when the DMA is in an optimum state. It does not require any modification to the scripts. The condition is decided at the DMA level.

The DMA can be programmed in two modes-conditional or always-true-for every channel, which provides complete flexibility. By default, the DMA is not in conditional mode.

The DMA condition is computed from the FIFO fill level and the various modes, as follows:

- When copy mode is selected, regardless of the transfer direction ('read' or 'write'), the condition is always true.
- In read mode, the condition is always true.
- In write mode, the condition is true when there are four bytes or less in the FIFO; it is false when there are more than four bytes. The 4-byte limit comes from the possibility of saving those bytes as MD with absolutely no impact on the bus accesses.

The aim at conditional yielding is to avoid splitting bus accesses (especially bursts).

47.4.12.2 Peripheral DMA Unit Programming

The peripheral DMA unit is connected to the Multi-Layer DMA Crossbar Switch of the ARM platform.

Its goal is to perform data transfers between any blocks connected to the DMA bus of this platform. These blocks are either peripherals or memories. The peripheral DMA could be seen as the ARM platform DMA controller.

The DMA performs data transfers in three modes:

Functional Description

- Read mode, where data is read from peripherals or from memory connected to the ARM platform and copied in a SDMA general register.
- Write mode, where data of a general register has to be written in a peripheral or a memory.
- Copy mode, where data is read from a peripheral (or memory) at a source address (PSA) and automatically written to a peripheral (or memory) at a destination address (PDA).

In copy mode, no SDMA general register is involved as transferred data only goes through the data register of the DMA.

The peripheral DMA has three addressing modes: frozen, incremented, and decremented, as follows:

- Frozen mode-When source or destination addresses are frozen, their value is not modified after a transfer. This mode is typically used for addressing peripheral FIFOs located at a fixed address.
- Incremented mode-When source or destination addresses are in incremented mode, after every transfer they are incremented by the number of bytes transferred.
- Decrement mode-In decremented mode, addresses are decremented by the number of bytes transferred.

The peripheral DMA registers are as follows:

- Two, 32-bit address registers (PSA and PDA) that respectively contain the source address for a read access and the destination address for a write access
- A 32-bit status register (PS) that contains information on the peripheral DMA configuration, such as the number of valid bytes in the data register, the error flag, the source and destination address mode, and so on.
- A 32-bit data register (PD) that stores data involved in a data transfer

47.4.12.2.1 Peripheral Source Address Register (PSA)

The source address register contains a pointer to a source peripheral or a memory associated with the next read data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (PSA) to store the address value
- A 2-bit register (stype) to store the source address mode (frozen, incremented, or decremented)
- A 2-bit register (ssize) to store the source target data path size (byte, half-word, or word)

Reading the register with the `ldf` instruction has no side effects and gives the address value of the next data that will be read by the SDMA during an `ldf MD` instruction. Writing the source address register may have side effects. If there is valid write data in the data register and the source address is changed, the write data is discarded. If the prefetch bit is set, a DMA read cycle is issued with the new address.

When PSA is to be written, you must specify the source target address mode, providing its size (byte, half-word, or word). This enables omission of the size field in all `ldf MD` instructions. When DMA performs a read cycle, its size is given by the value of the PSA source size register (`ssize`). If source is a memory in incremented mode, first programmed in word mode (`stf PSA|SZ32I`), and if an SDMA script needs to read bytes from this memory, the size of the source target must be updated before executing new accesses. The source address mode and its size are given by labels added to the `stf PSA` instruction as described in the write section. The `ssize` and `stpe` registers are part of the DMA status register (`PS`).

Writing to PSA may issue an immediate error if the source size is not compatible with the value to be written into the PSA register. For instance, writing a 2 in PSA and specifying that it is memory-accessed in word mode creates an immediate error.

47.4.12.2.2 Peripheral Destination Address Register (PDA)

The destination address register contains a pointer to a source peripheral or a memory associated with the next write data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (`PDA`) to store the address value
- A 2-bit register (`dtype`) to store the destination address mode (frozen, incremented, or decremented)
- A 2-bit register (`dsize`) to store the destination target data path size (byte, half-word, or word)

Reading the register with the `ldf` instruction has no side effects, and gives the address value of the next data that will be written by SDMA during an `stfMD` instruction. Writing the destination register has no side effect. Similar to the PSA register, the destination address mode and source are specified in the `stf PDA` instruction and may also generate an error in case of incorrect programming.

47.4.12.2.3 Peripheral Data Register (PD)

The data register of the peripheral DMA is a 32-bit register. When the destination address is correctly set up, any writing to `PD` will automatically flush the new input data.

Functional Description

The number of SDMA bytes that will be transferred is given by the PDA size register. Unlike other SDMA DMAs, PD is not a FIFO: It is not used to accumulate bytes that from the SDMA and must be packed before being sent to external memories. In read mode, and if the source address is correctly set up, an ldf instruction will empty PD. If a prefetch is required along with the instruction, the DMA will initiate a new read transfer.

Reading PD in prefetch mode only stalls the SDMA when the prefetched data is not yet available. Writing PD only stalls the SDMA if the previous write operation was not completed. As soon as the previous operation is over, the acknowledge is sent back to the SDMA RISC engine.

An error flag-part of PS-is set when an external access fails. The error is thus reported to the next SDMA instruction that involves the peripheral DMA.

47.4.12.2.4 Peripheral State Register (PS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer.

Although all PS fields can be written by an stf instruction, it is recommended to access only the error bit (to reset it). Modifying other PS fields will provide an un-guaranteed DMA behavior.

The initialization value of PS is 0, and it consists of the following structure:

Table 47-28. PS Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	ssize		stype		dsize		dtype	
W																
R	0	0	0	0	0	d	e		0	0	0	0	0	n		
W																

Table 47-29. PS Field Descriptions

Field	Description
31-24	Reserved
23-22 ssize	Source Target Size. Determines the size of the read transfers on the external bus. It should match the accessed device characteristics. 00 reserved 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

Table continues on the next page...

Table 47-29. PS Field Descriptions (continued)

Field	Description
21-20 stype	Source address Mode. Determines whether PSA is incremented, decremented, or kept unmodified after every read from the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decrement Mode 11 <i>reserved</i>
19-18 dsize	Destination Target Size. Determines the size of the write transfers on the external bus. It should match the accessed device characteristics. 00 <i>reserved</i> 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
17-16 dtype	Destination address Mode. Determines whether PDA is incremented, decremented, or kept unmodified after every write on the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decrement Mode 11 <i>reserved</i>
15-11	Reserved
10 d	Direction Flag or DMA Mode. DMA is in write mode when data was written into PD by stf PD instructions, or if a previous DMA cycle on the external bus was a write access. Writing PDA or PSA does not change the DMA mode. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by the SDMA with an ldf PD instruction. Reading PDA or PSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 <i>reserved</i> 10 Error mode 11 Error read
7-3	Reserved
2-0 n	number of bytes in PD

NOTE

dtype, dsize, stype, and ssize are updated when PSA and PDA are written.

47.4.12.2.5 Peripheral DMA Write (stf)-Write Mode

When written by an stf instruction, the function code bits are interpreted as follows:

Table 47-30. STF Code Bits

Register	7	6	5	4	3	2	1	0	
PSA	s		p	ar	am		sz		
PDA									
PD			pdsel						
PS			pssel						

Table 47-31. STF Code Bits Field Descriptions

Field	Description
7-6 s	Functional Unit selector 11 for Peripheral DMA
5 p (PSA)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
3-2 am (PSA/PDA)	Address Mode. Determines how PSA or PDA is modified after every read or write access to the PD. 00 Frozen-Address registers are not modified after the transfer. 01 Incremented-Address registers are incremented by the number of transferred bytes. 10 Decrement-Address registers are decremented by the number of transferred bytes. 11 Updated-PSA and PDA are not modified. Either address mode is not modified, but the width of the data path is updated by the sz field.
1-0 sz	Transfer Size 00 <i>reserved</i> 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
5-0 pdsel	PD access selector 001000 is the only valid option
5-0 pssel	PS access selector 111111 writes to PS 001100 only clears the error flag in PS

Due to the large number of possible stf instructions, the following table provides only a short list of all the possible write instructions:

5 p (PD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA

Table continues on the next page...

Table 47-34. LDF Code Bits Descriptions (continued)

Field	Description
	1 PDA
4 copy (PD)	Copy Mode 0 standard access 1 copy mode access
3 a	Register Set selection 0 PSA or PDA 1 PD or PS
5-0 pssel	PS access selector 111111 is the only valid option to read PS

Table 47-35. Peripheral DMA LDF Instruction List

Binary	Assembly	Comments
11_0_0_0_000	ldf Rn, PSA	Reads 32-bit of PSA value
11_0_1_0_000	ldf Rn, PDA	Reads 32-bit of PDA value
11_0_0_1_000	ldf Rn, PD	Reads programmed source size bytes of PD (0-extended)
11_1_0_1_000	ldf Rn, PDIPF	Reads programmed source size bytes of PD (0-extended), and starts a prefetch at PSA address.
11_0_1_1_000	ldf Rn, PDICOPY	Starts a copy transfer from the source target at the PSA address to the destination target at the PDA address. No data transmits through Rn, but Rn contents are lost (Rn is loaded with PD temporary contents that are <i>not</i> the copied data).
11_111111	ldf Rn, PS	Reads 32-bit of PS value

NOTE

When reading PD, size information is not important: It is embedded in the ssize field of the PSA register. If ssize is 1, 2, or 4, the one, two, or four bytes is transferred from PD to Rn. Read data is 0-extended.

47.4.12.2.7 Peripheral DMA Unit Copy Mode

Like burst DMA, the peripheral DMA unit has a copy mode that is used when data transfers do not involve SDMA general registers.

Data is read from the source target at a PSA address, stored in PD, and then automatically flushed to the destination target at the PDA address. Copy mode is only available for transfers that involve two targets of the same data path width.

Functional Description

Since copy mode is invoked with an ldf instruction, the *loaded* general purpose register loses its previous contents. (However, the new contents are unpredictable as they depend on temporary values that are seen on the external DMA bus.)

47.4.12.2.8 Error Management

Peripheral DMA generates two kinds of errors: the immediate error that sanctioned incorrect register programming; and the error triggered by the previous access and stored in the error flag of PS until a DMA instruction is executed.

47.4.12.2.8.1 Immediate Errors

The following table lists all incorrect DMA register setups.

Table 47-36. Immediate Errors with Peripheral DMA

Rn[1:0] values	DMA instruction	Comments
0x01 0x11	stf Rn, PSAISZ16IF stf Rn, PSAISZ16II stf Rn, PDAISZ16IF stf Rn, PDAISZ16II	If PSA points to a half-word peripheral or to a half-word address in memory, its value must be 0 modulo 2.
0x01 0x10 0x11	stf Rn, PSAISZ32IF stf Rn, PSAISZ32II stf Rn, PDAISZ32IF stf Rn, PDAISZ32II	If PSA points to a word peripheral or to a word address in memory, its value must be 0 modulo 4.
PSA[1:0]-PDA[1:0]	DMA instruction	Comments
0x01 0x10 0x11	stf Rn, PSAISZ32IU stf Rn, PDAISZ32IU	When PDA or PSA is updated and becomes a pointer to a word address in memory, its content must be 0 modulo 4.
0x01 0x11	stf Rn, PSAISZ16IU stf Rn, PDAISZ16IU	When PDA or PSA is updated and becomes a pointer to a half-word address in memory, its content must be 0 modulo 2.
Read/Write PD instruction	Comments	
stf Rn,PD ldf Rn,PD		If PDA size (dsize) has never been set up before an stf PD instruction (dsize=0) If PSA size (ssize) has never been set up before an ldf PD instruction (ssize=0)
ldf Rn,PDICPY		Copy mode is possible only between two targets whose data path width is identical. It is P8↔P8, P16↔P16, or P32↔P32 regardless of the way the address registers are incremented.

47.4.12.2.8.2 Data Transfer Errors

When PSA and PDA are correctly set up, the only error that may arise for an ldf PD or stf PD instruction would be the error of the previous DMA cycle.

Error handling is driven by a single consideration: When an error occurred during a data read on the DMA interface, this error should appear as a transfer error to the core when the core attempts to retrieve the data that was not successfully read from the accessed device (memory or peripheral).

When an error occurred during a write access to the DMA interface, the data is still available in PD and should not be destroyed by subsequent core accesses: The core must be warned about the error issue.

There are three error handling mechanisms for each case: [Read Error \(First Phase\)](#), [Write Error and Read Error \(Second Phase\)](#), and [Copy Mode Errors](#) handling.

47.4.12.2.8.3 Read Error (First Phase)

If an error occurred during a prefetch command, the peripheral DMA enters its ERROR READ mode (PS[9:8]=11). In this mode, the error is reported on the next ldf PD instruction and writing PSA, PDA, or PD will cancel the error flag.

The block returns no error mode and instructions are normally executed (a DMA cycle may be triggered). Similarly, initiating a copy transfer will reset the error flag and start a copy transfer. The following table details which instructions can be executed in this mode.

Table 47-37. Possibilities in ERROR READ Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA (IU IPF) stf rn, PDA ldf rn, PDICOPY	NO	Error mode is reset, PSA or PDA are updated, or a write cycle is started. For the ldf PDICOPY, a copy loop is executed.
stf rn, PS	NO	PS is updated.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Error of the previous read access is reported here and the peripheral DMA enters its ERROR mode.

47.4.12.2.8.4 Write Error and Read Error (Second Phase)

The peripheral DMA enters its ERROR mode (PS[9:8]=10) when the previous DMA write cycle failed, or, as explained in [Read Error \(First Phase\)](#), when an ldf PD is executed while the block is in ERROR READ mode. When a DMA cycle failed, address registers (PSA, PDA) are not modified and continue to point to the problematic address. In ERROR mode, stf instructions may raise an immediate error, and ldf instructions will not (as detailed in the table below).

Table 47-38. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA stf rn, PDA	YES	Any attempt to modify PD, PSA, or PDA will raise an immediate error, and the peripheral DMA stays in ERROR mode. When address registers are write accessed, an error is returned.
stf rn, PS	NO	This is the only way to exit the ERROR mode. PS[3] must be reset by an stf PS instruction.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Whatever the DMA direction (read or write), an ldf rn, PD instruction will show an immediate error.

47.4.12.2.8.5 Copy Mode Errors

Because copy mode is a write access that follows a read access, there are two possible cases of bus error.

When the read access incurs a bus error, the peripheral DMA behaves exactly as described in [Read Error \(First Phase\)](#) and [Write Error and Read Error \(Second Phase\)](#) : It enters its ERROR READ mode, and so on.

When the error occurred during the write access of the copy transfer, the DMA enables the core to retrieve the data that was read because it is assumed the read from the peripheral removed the data from its source device. Therefore, the data to be flushed is still in PD. Any subsequent access to PD triggers an error to the core, which should execute its error handling procedure.

Once the ERROR mode is left (after writing to PS), it is possible for the core to retrieve the data in PD with an ldf instruction or try to flush PD contents once again (for example, when the error was due to a full FIFO and the script waited for the FIFO to be emptied) with another ldf instruction in copy mode. This latter instruction detects that there is valid data in PD, tries to flush it, and thus skips the read phase of the copy instruction. This is a different behavior from the usual stf PD instruction that overwrites PD with the selected General Purpose register contents. The same mechanism can be used any time PD holds data that is not written because of a bus error on the DMA interface; when the data was written via a copy instruction, or via the usual stf PD instruction.

47.4.12.2.8.6 Error Check Example

The following code illustrates an example checking for both immediate and data transfer errors on a store to the PD register. The first bdf instruction checks for an immediate error, but if a data transfer error occurred it is reported until the next instruction to access the Peripheral DMA. A second check of the error flags is done after the ldf PS

instruction. The value of PS here can be ignored. The act of reading any register in Peripheral DMA while it is in an error mode that returns the error to the core to set either the SF or DF flag. Any error returned on an ldf command sets the SF flag and any error returned on an stf instruction sets the DF flag. This can create a situation as shown in the example where a bus error during a DMA write which would normally be considered as a destination fault is reported as a source fault because the error was reported to the SDMA core during an ldf instruction.

Peripheral DMA Error Check

```

    clrf    0           // Clear SF and DF flags
    stf    R4, PD      // Write data to memory
    bdf    error_routine // Check for immediate error from write to PD.
    ldf    r3, PS      // Read PS (PS value in R3 can be ignored)
    bsf    error_routine // Check for bus error from "stf R4,PD"
                // SF is set because it is a ldf instruction, even though
                // the original error was a destination fault

```

47.4.12.2.9 Peripheral DMA Unit Prefetch/Flush Management

There is no flush bit because every time data is stored in PD by a stf PD instruction—assuming PDA is correctly programmed—it is automatically flushed to the destination.

An acknowledge is returned in the cycle of the DMA instruction, and the SDMA is only stalled by an instruction that addresses the peripheral DMA when the previous DMA access is not over.

47.4.12.3 OnCE and Real-Time Debug

The On-Chip Emulation block (OnCE) is the debug interface to the SDMA.

It supports the access to all core internal devices (registers, memory, and so on), and provides a set of mechanisms that control the core. The OnCE is accessed by JTAG ports at the chip's board level, or by the host via its peripheral bus.

To reduce the size of the hardware material involved, all tasks supported by the OnCE are performed on the SDMA core. The architecture of the SDMA OnCE is relatively simple and very flexible.

The commands supported by the SDMA OnCE are listed in the following sections.

47.4.12.3.1 Memory and Register Access

A set of mechanisms is provided to access SDMA memory and register locations. Both reading and writing are allowed. The access is supported if the processor is in debug mode.

Those registers can also be accessed through the ARM platform Control interface when the OnCE is controlled by the ARM platform, as described in the "Using BP" section.

47.4.12.3.2 Hardware Breakpoints

An event detection unit is implemented to support memory breakpoints. The unit watches the data exchanged between the SDMA memory bus and the core.

A debug request is sent to the core when matching conditions occur. The unit supports mixed conditions based on address range, access type, and data value. Event detection unit configuration registers are memory mapped in the SDMA space (see [ARM platform Channel 0 Pointer \(SDMAARM_MC0PTR\)](#)): You can modify them through a regular memory access or the ARM platform control interface.

47.4.12.3.3 Watchpoints

One output pin is provided to monitor matching trigger conditions that are defined in the event detection unit.

47.4.12.3.4 Software Breakpoints

The SDMA instruction set contains a software breakpoint. Upon executing a software breakpoint instruction, the core suspends normal execution and enters debug mode.

No hardware step execution mode is implemented in the OnCE, but this feature may be implemented at the software level with this instruction.

47.4.12.3.5 Core Control

Commands are provided to monitor and control processor activity. You can halt the core, rerun the core from another address location, and get processor status.

Any hardware breakpoint on the instruction bus is not supported, but this feature may be implemented by inserting a software breakpoints program.

47.4.13 The OnCE Controller

The OnCE controller receives commands from the ARM platform or from the JTAG controller. Each command is interpreted before being sent to the core.

47.4.13.1 OnCE Commands

A small set of commands supports the communication between the OnCE and the external world.

This command set enables you to perform any of the following tasks: control processor activity, save core context, and execute an SDMA instruction from the OnCE. Combined together, these tasks perform more complex commands.

A full OnCE command contains a 4-bit instruction (the OnCE command opcode) and a variable length data field (the OnCE data). During command execution, the OnCE data is transferred in a OnCE internal register before being exchanged with the SDMA. Some data values are also exported. This mechanism creates a link between the processor and the external world. Nine commands are defined: The following table presents their formats.

Table 47-39. OnCE Command Opcode Values

Instruction Opcode	Name	Action	Register	Data Field Size	Mode
0000	rstatus	Reads the OnCE status register	STATUS	16-bit	normal/debug
0001	dmov	Updates general register GReg1	GREG1	32-bit	debug
0010	exec_once	Runs the instruction from the SDMA instruction register	INSTRUCTION	16-bit	debug
0011	run_core	Returns to normal execution	BYPASS	1-bit	debug
0100	exec_core	Returns to normal execution via a jump instruction that specifies the new address	INSTRUCTION	16-bit	debug
0101	debug_rqst	Stops the core after execution of current instruction	BYPASS	1-bit	normal
0110	rbuffer	Reads the real time buffer	RTB	32-bit	normal/debug
0111-1110	reserved	Reserved	BYPASS	1-bit	normal/debug
1111	bypass	Bypasses TARM platform controller	BYPASS	1-bit	normal/debug

Each instruction corresponds to a specific action performed on the OnCE. The nature of the associated data field is clearly identified. The `dmov` command is followed by a 32-bit data value (which is a data value for the SDMA); the `exec_once` and the `exec_core` commands are followed by a 16-bit data value (which is an instruction for the SDMA); the `rstatus` command is followed by a 16-bit control value (which is the content of the OnCE status register); the `rbuffer` command is followed by a 32-bit data value. The

debug_rqst and the run_core commands are followed by a single bit data field (this is a bypass value). Finally, the bypass instruction enables the SDMA JTAG TAP controller to be daisy-chained with another JTAG TAP controller. This is a JTAG-only feature. The set of commands is simple, but enables you to perform any possible task on the SDMA during a debug process.

47.4.13.2 Sending Commands to the OnCE Controller

The JTAG access is the standard access to the OnCE, but sometimes the JTAG is not available to fix some bugs (if the chip is in production for instance), an additional access is then required. Therefore, one ARM platform access to the OnCE is provided.

47.4.13.2.1 Using the JTAG Interface

A serial access is performed through the five JTAG pins TCK, TRST, TMS, TDI, and TDO. A Test Access Port controller is provided to decode the TMS control signal.

It produces shift-enable signals (shift_ir and shift_dr), and updates enable signals (update_ir and update_dr). It is fully compliant with the IEEE 1149.1 testability (JTAG) standard.

During the shift_ir state, the command opcode is shifted into the OnCE controller (for example, the signal from the TDI pin is shifted into the command register and the TDO pin receives the signal shifted out). After transferring the four bits of the command, an update_ir signal is asserted and the command is decoded. The target data register is now clearly identified and the corresponding control signal is produced, as follows: bypass enable signal (bp_en), instruction enable signal (inst_en), data enable (data_en), and status enable signal (stat_en).

During the shift_dr state, the TDI signal is shifted into one of the following target registers: bypass register (1 bit), SDMA instruction register (16 bits), SDMA data register (32 bits), or OnCE status register (16 bits). The TDO pin is connected to the output of the selected register to receive the signals shifted out.

The JTAG access is disabled when the ARM platform access is enabled.

47.4.13.2.2 Using the ARM platform

The ARM platform access to the OnCE is not the standard access, but it is required if the JTAG is not available.

For example, if the SDMA ROM is out of use on a chip in production, and the ARM platform needs to download new code and restart the SDMA, the OnCE can easily perform this operation. This type of debug operation justifies the use of an ARM platform access to the OnCE.

To drive the OnCE, the ARM platform uses some registers contained in the ARM platform Control block of the SDMA. These registers are accessed through the ARM platform peripheral bus. Most of these registers are connected to another register in the OnCE controller. Thus, accessing one of these registers is equivalent to accessing the associated register in the OnCE controller.

The set of registers in the ARM platform Control block is listed below:

- **ONCE_ENB** register (1 bit, read/write)-This 1-bit register enables the ARM platform access to the OnCE. When this bit is set, the signals from the JTAG are ignored. When it is cleared, all writing operations to the following registers through the Host Control interface are ignored. This register is reset on a JTAG reset.
- **ONCE_CMD** register (4 bits, read/write)-This 4-bit register receives the command opcode. It is connected to the command register in the controller. A write access to this register causes the associated command to be executed on the OnCE. For example, after writing "0001" in this register, a dmov command is executed.

NOTE

On the ARM platform side, the rstatus and bypass commands are not supported. This register is reset on a JTAG reset.

- **ONCE_DATA** register (32 bits, read/write)-This 32-bit register is connected to the SDMA data register. This register is used when executing a dmov or rbuffer command.

NOTE

Before requesting a dmov command, the 32-bit data to transfer must be written in the ONCE_DATA register. At the end of the execution, the register is updated with GReg1 former value. This register is reset on a JTAG reset.

- **ONCE_INSTR** register (16 bits, read/write)-This 16-bit register is connected to the SDMA instruction register. This register is used when executing an exec_core or an exec_once command.

NOTE

Before requesting an exec_core or an exec_once command, the appropriate instruction must be written in the ONCE_INSTR register. This register is reset on a JTAG reset.

- ONCE_STAT register (16 bits, read only)-A read access to the ONCE_STAT register returns the content of the OnCE status register (OSTAT). This register is read only.
- The bypass register is not useful when the ARM platform controls the OnCE, therefore no register is defined in the ARM platform Control block to access the bypass register.

47.4.13.2.3 Conflicts Between the JTAG and the ARM platform Accesses

When ARM platform access to the SDMA OnCE is enabled (that is, when the bit in the ONCE_ENB register is set), the JTAG access is disabled. This guarantees that the block is not accessed at the same time on both sides.

It is possible to check whether the JTAG access to the SDMA OnCE is enabled from the JTAG port. When the JTAG access is disabled, the SDMA TDO always returns 1. The check requires the following steps:

- Execute a dmov command from debug mode (with neither 0xffffffff nor 0x0 as dmov value: 0x5a5a5a5a is good).
- Execute another dmov command (the value here is not important).
- The returned value from the latter dmov command should be the original one if the JTAG access is enabled; if it is 0xffffffff instead of the original input value, this means the JTAG access is disabled.

47.4.13.3 Executing a Command from the OnCE

All the commands defined in [OnCE Commands](#) can be accessed through the JTAG. The ARM platform can access all these commands except the rstatus command.

On the ARM platform side, the OnCE status is directly accessed by reading the ONCE_STAT register.

47.4.13.3.1 Nature of the Commands

Two types of commands may be distinguished. First, there are two commands that do not interact with the core: rstatus and rbuffer. Those commands may be requested at any time: They do not depend on the core status.

NOTE

Each of these commands exports a data value or a status value from the SDMA.

There are also commands that interact with the core: `dmov`, `run_core`, `exec_core`, `exec_once`, and `debug_rqst`. These commands are core status dependent, as follows:

- During user mode only the `debug_rqst` is taken into account.
- During debug mode, all these commands are taken into account except the `debug_rqst`. For example, an `exec_once` command requested while not in debug mode has no effect.

47.4.13.3.2 Execution Request

The SDMA starts executing a task in debug mode when requested by the OnCE controller. The execution starting time depends on the type of access used to communicate with the OnCE.

If the JTAG is used, the request is sent after decoding the `update_dr` state in the TAP controller. Therefore, always cross this state when sending a command through the JTAG. If the OnCE is driven from the ARM platform side, the request is sent after detecting a write access to the `ONCE_CMD` register. All the registers involved in this operation must be loaded first.

The following is an example of an `exec_core` command execution from the ARM platform side: After writing '010' in the `ONCE_CMD` register, the OnCE controller asks the SDMA to execute the instruction contained in the `ONCE_INSTR` register. The instruction involved should be available in the `ONCE_INSTR` register before the beginning of the execution.

47.4.13.3.3 Command Execution

The following list shows the commands and details how each command is executed:

- `rstatus` command execution-The `rstatus` command exports the content of the OnCE status register (OSR). If the JTAG is used, the status information is captured in the OnCE status register during the `capture_dr` state, and shifted out after 16 TCK clock cycles in the `shift_dr` state. The `rstatus` command is not supported on the ARM platform side, but a status register is provided instead. The `rstatus` may be performed in both debug and user modes.
- `dmov` command execution-The `dmov` command accesses SDMA internal registers. Executing a `dmov` instruction exchanges the 32-bit data values between the SDMA data register and the general register `GReg[1]`.
- If the JTAG is used, the content of `GReg1` is captured in the SDMA data register during the `capture_dr` state, then it is shifted out after 32 TCK clock cycles in the `shift_dr` state. During the `update_dr` state, `GReg1` is updated with the new, shifted-in 32-bit data value. If the OnCE is driven from the ARM platform side, the data values

contained in GReg1 and the SDMA data register are exchanged after detecting a write access to the ONCE_CMD register. The ONCE_DATA register must therefore be loaded first.

- **exec_once** command execution-The **exec_once** command executes the instruction loaded in the SDMA instruction register. The command may only be requested from debug mode. The SDMA returns to debug mode at the end of the execution.
- Change of flow instructions as well as instructions that may cause a context switch are not supported: The comprehensive list comprises **done/yield/yiedge** (except **done 5**), **BF**, **BT**, **BSF**, **BDF**, **JMP**, **JSR**, **JMPR**, **JSRR**, **RET**, and **LOOP**, as well as all the illegal instructions.

No other command should be requested before the SDMA returns to debug mode. The SDMA status (for example, whether it is in debug mode or not) can be detected by polling with the **rstatus OnCE** command, monitoring the **debug_mode** pin, or checking the [OnCE Status Register \(SDMAARM_ONCE_STAT\)](#) register via the ARM platform control interface.

NOTE

Most of the instructions are single-cycle, which omits the step of polling the status. Loads and stores to DMA units are typical instructions that might require this polling.

If the JTAG is used, the 16-bit instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the **shift_dr** state. A request is sent to the core when the **update_dr** state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the request is sent to the SDMA when detecting a write access to the ONCE_CMD register. The ONCE_INSTR register must be therefore be loaded first.

- **run_core** command execution-The **run_core** command leaves debug mode and resume normal program execution. The next instruction executed is the last instruction decoded before entering debug mode. Be sure to restore core context before re-running the core. This procedure is detailed in [Restoring the Context](#).
- If the JTAG is used, a 1-bit bypass value is shifted in the **bypass** register in the **shift_dr** state. The SDMA is rerun when the **update_dr** state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the core is rerun when detecting a write access to the ONCE_CMD register.
- **exec_core** command execution-The **exec_core** command resumes program execution from any address. The 16-bit instruction provided with the **exec_core** overwrites the last instruction decoded before entering debug mode. This command is designed to support change of flow instructions, so that a program execution can be restarted

from any address. After executing an `exec_core` command, the SDMA leaves debug mode. The `exec_core` command is usually used with a `jmp` instruction.

- If the JTAG is used, the 16-bit branch instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the `shift_dr` state. The SDMA is rerun when the `update_dr` state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the SDMA reruns when detecting a write access to the `ONCE_CMD` register. The `ONCE_INSTR` register must therefore be loaded first. For example, to restart the SDMA from the program address 0x100, the instruction loaded should be a jump to address 0x100 instruction.
- `debug_rqst` command execution-The `debug_rqst` command puts the SDMA in debug mode. If the JTAG is used, a 1-bit bypass value is shifted in the bypass register during the `shift_dr` state. A debug request is sent to the SDMA when the `update_dr` state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the debug request is sent when detecting a write access to the `ONCE_CMD` register. When the SDMA is already in debug mode, this command is simply ignored.
- `rbuffer` command execution-The `rbuffer` command exports the content of the real time buffer (RTB). If the JTAG is used, the content of the real time buffer (RTB) is captured in the SDMA data register during the `capture_dr` state. The register is completely shifted out after maintaining the `shift_dr` state during 32 TCK clock cycles. If the OnCE is driven from the ARM platform side, the content of the RTB is captured in the `ONCE_DATA` register after detecting a write access to the `ONCE_CMD` register.
- `bypass` command execution-This command is only available from the JTAG interface. It enables daisy-chaining of the SDMA JTAG TAP controller with other JTAG TAP controllers. This command does not change the SDMA state and can be executed in any mode (run, debug, or sleep). It selects the bypass register of the TAP controller.

47.4.13.4 Registers Descriptions

See [SDMACORE](#), and [SDMAARM](#), for detailed information on each register.

47.4.13.4.1 Event Cell Counter Register (ECOUNT)

The event cell counter register is a 16-bit register that contains the number of times minus one that an event detection occurs before generating a debug request.

This register should be written before attempting to use the event detection counter during an event detection process. The event cell counter register is cleared on a JTAG reset.

47.4.13.4.2 Event Cell Address Registers (EAA or EAB)

The event cell contains two address registers—the event cell address register (a), called EAA, and the event cell address register (b), called EAB. Every address register is a 16-bit register that stores a user-defined address value. This value computes one of the following address conditions: `addra_cond` or `addrb_cond`. Every address register is cleared on a JTAG reset.

47.4.13.4.3 Event Cell Address Mask Register (EAM)

The event cell address mask register is a 16-bit register that contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before comparing addresses.

NOTE

There is a common address mask value for the two address comparators. If bit i of this register is set, then bit i of the address value latched from the memory bus does not influence the result of the address comparison. The event cell address mask register is cleared on a JTAG reset.

47.4.13.4.4 Event Cell Data Register (ED)

The event cell data register is a 32-bit register that contains a user-defined data value. This data value is an input for the data comparator, which generates the `data_cond` condition.

The event cell data register is cleared on a JTAG reset.

47.4.13.4.5 Event Cell Data Mask Register (EDM)

The event cell data mask register is a 32-bit register that contains a user-defined data mask value. This mask is applied to the data value latched from the memory bus before comparing data.

Setting bit i of the event cell data mask register means that bit i of the data value latched from the address bus does not influence the result of the data comparison. The event cell data mask register is cleared on a JTAG reset.

47.4.13.4.6 Real Time Buffer Register (RTB)

The real Time Buffer register is a 32-bit register that stores and retrieves run-time information without putting the SDMA in debug mode.

Refer to [Real Time Buffer](#) for more details.

47.4.13.4.7 Event Control Register (ECTL)

The event cell control register is a 16-bit register that defines cell event occurrence conditions.

The event cell control register is cleared on a JTAG reset. See also [OnCE Event Detection Unit](#) for more details.

47.4.13.4.8 Trace Buffer (TB)

The Trace Buffer register retrieves the information in the Trace Buffer.

See [Trace Buffer](#) for more details.

47.4.13.4.9 OnCE Status Register (OSTAT)

The OnCE status register is a 16-bit register that contains processor and event detection unit status. The OSTAT is a read-only register.

Refer to [OnCE Status Register \(SDMAARM_ONCE_STAT\)](#) for detailed description of the individual fields in the OSTAT register.

The following figure shows the OSTAT structure.

Table 47-40. OnCE Status Register (OnCE)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PST[3:0]				RCV	EDR	ODR	SWB	MST					ECCR[2:0]		

Where PST[3:0] is the SDMA core state, RCV is set when the real-time buffer (RTB) is modified. EDR, ODR, and SWB are set, respectively, when the SDMA has entered debug mode because of an external debug request, a OnCE debug_rqst command, or a software breakpoint. MST is set when the OnCE is controlled from the ARM platform control interface, and when ECCR is a three-flag set that shows the event cell condition(s) that put the core in debug mode. The OSTAT never provides more than one reason for entering debug mode.

There are two ways of accessing OSTAT content, as follows:

1. Send an rstatus command to the OnCE controller through the JTAG, or read the ONCE_STAT register through the ARM platform access. Executing the rstatus command through the JTAG can be performed in both user and debug modes.
2. Perform an SDMA read access to the location in the SDMA core memory map (OSTAT register) debug mode using the exec_once command. With this method of access, the SDMA state reflected by the PST (processor status bit) is always DATA.

The register may also be accessed by a running application.

47.4.13.5 JTAG Interface Requirements

Because the signals received from the JTAG (running on TCK) are transferred to the OnCE controller (running on the SDMA clock), a synchronization mechanism is required.

47.4.13.5.1 TCK Speed Limitation

In the JTAG top-level layer, the TDO signal is always captured on a TCK falling edge. To guarantee a stable TDO signal from the SDMA during this operation, a falling edge detection is performed on TCK.

Before being latched in the *I* flip-flop (see [Figure 47-11](#)) on TCK falling edge, the TDO signal must be stable at the input of the flip-flop. This condition is verified if the TCK period is superior to the following delay:

worst-case edge detection delay + negative-edge signal propagation delay + JTAG top-level logic propagation delay

The frequency relationship, $TCK < CLK/8$, limitation guarantees that all operations are performed as expected.

47.4.13.5.2 Synchronization Implementation

The figure found here shows the synchronization mechanism.

Flip-flops tck0, tck1, and tck2 perform falling- and rising-edge detections on TCK. They generate the posedge_detected and negedge_detected nets that are used to sample the TDI and TMS inputs into the respective tdi and tms flip-flops, and update the tdo flip-flop to yield the TDO output. In the design, the only signal that might go metastable is the output of the tck0 flip-flop. This signal is captured in the tck1 flip-flop and no logical operation is performed on it to minimize a metastability propagation risk.

The TDI and TMS flip-flops also cannot go metastable: The propagation time of the rising-edge detection signal through tck0, tck1, and tck2 guarantees that the TDI and TMS inputs are stable when captured in the TDI and TMS flip-flops.

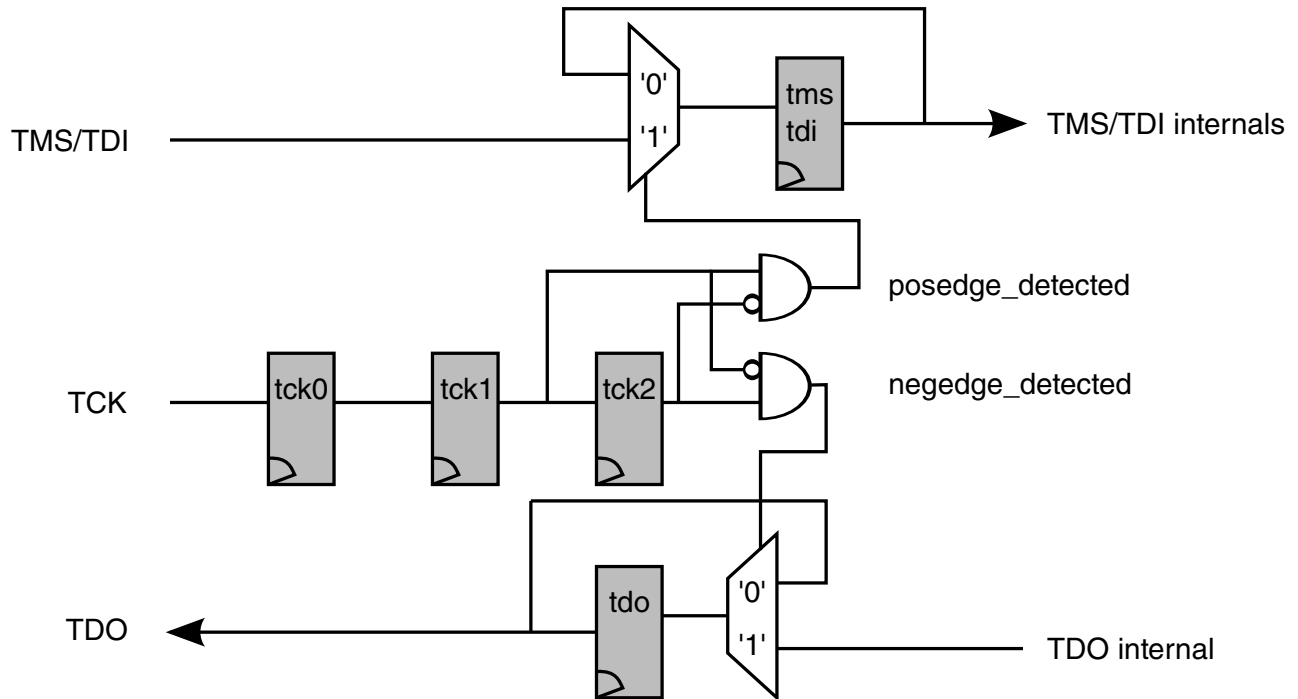

Figure 47-11. OnCE Synchronization Layer

The following figure shows synchronization timings. It takes three CLK clock cycles to synchronize TDI on the SDMA clock.

Figure 47-12. Synchronization Timings

47.4.13.5.3 JTAG Controller Start-Up Recommended Procedure

To ensure correct TAP controller initialization, it is recommended to use the following procedure:

1. Assert JTAG reset TRSTB (for example, set low).
2. Set TMS low.
3. Wait for 1 TCK clock.
4. Release JTAG reset TRSTB (for example, set high).
5. Wait for a minimum of five TCK cycles.

47.4.14 Using the OnCE

This section provides the elements necessary to run the OnCE during a debug process.

In addition to the basic set of commands described in [OnCE Commands](#), more complex commands can be built to meet users' requirements.

47.4.14.1 Activating Clocks in Debug Mode

For power consumption issues, some clocks in the SDMA are disabled when not needed.

This is the case for instances when the SDMA is in sleep mode. Clock gating management depends on the interface used to control the OnCE.

- For the JTAG access, the SDMA clock gating must be turned off via the `clk_gating_off` input.
- For the ARM platform access, the SDMA clock gating is automatically turned off when the ARM platform access is enabled (see [OnCE Enable \(SDMAARM_ONCE_ENB\)](#)).

47.4.14.2 Getting the Current Status

Most of the commands the OnCE supports have an impact on the status of the SDMA.

It is not permissible to request the execution of an instruction on the SDMA from the OnCE while the SDMA is not in debug mode. Such a violation may cause unpredictable behavior, and it might be necessary to reset the SDMA.

Therefore, the value of the PST bits provided in the OnCE status register should always be checked before sending any request to the SDMA.

47.4.14.3 Methods of Entering Debug Mode

A debug request may be asserted at any time, but it is not always taken into account immediately. Debug mode cannot be entered in the middle of an instruction, or during the save or restore states of a context switch.

The request is ignored when the core is already in debug mode. Refer to [Figure 47-4](#), which shows all possible transitions to the debug state, as there are several ways to enter debug mode.

47.4.14.3.1 External Debug Request During Reset

To enter debug mode after exiting reset, the external debug line has to be maintained high. This line is handled by the JTAG top-level block.

NOTE

The SDMA detects the debug requests only if the SDMA clock is running (see [Activating Clocks in Debug Mode](#)). The debug request line should be not be maintained high when the SDMA is in debug mode.

NOTE

The `debug_rqst` command (from the OnCE command set) is not supported during system reset.

47.4.14.3.2 Debug Request During Normal Activity

During normal activity, the SDMA enters debug mode when the following is true:

1. If the debug request line from the JTAG top-level is asserted, or
2. If the OnCE controller receives a `debug_rqst` command.

The `debug_rqst` command can be sent by the JTAG access or by an access on the ARM platform side (if the ARM platform access is enabled).

47.4.14.3.3 Software Breakpoint Instruction

The SDMA enters debug mode at the end of the execution of a software breakpoint instruction. This instruction must be inserted in program flow executed by the core.

47.4.14.3.4 Event Detection Unit Matching Condition

If the event detection is enabled, a debug request is sent to the core after detecting a matching condition on the SDMA memory bus.

See [OnCE Event Detection Unit](#) for more details.

47.4.14.4 Executing Instructions in Debug Mode

The OnCE supports a mechanism to execute instructions in debug mode. If the SDMA is in debug mode, then the `exec_once` command can be used to execute an SDMA instruction from the OnCE controller. The SDMA returns to debug mode at the end of each execution.

Some instructions are not supported by the `exec_once` command: `done/yield/yiedge` (except `done 5`), `BF`, `BT`, `BSF`, `BDF`, `JMP`, `JSR`, `JMPR`, `JSRR`, `RET`, and `LOOP`, as well as all the illegal instructions are not supported.

NOTE

While instructions are executed in debug mode from the OnCE, the program counter of the SDMA is not incremented.

47.4.14.5 Command Sequences Examples

This section provides examples of command sequences that run the SDMA in debug mode. These sequences are available for both the ARM platform and JTAG accesses.

The following presents the syntax used in this section. The data field provided with each command is put in parenthesis with the command name. A '-' is used if the data field provided is a *don't care* value.

```
my_command(data_field);           // executing my_command with a data field
my_command(-);                   // executing my_command with a don't care data field
```

The value returned by the command (if there is one) is referred by an assignment. In case the value returned by the command is not used, the assignment is omitted. For an ARM platform access, the value returned (it is always a data value) is obtained by reading back into the SDMA data register.

```
data_out = my_command(data_in); // returning a data value
```

To clarify the syntax, the instructions' opcodes are referred to by their names. In practice, use the corresponding 16-bit encoding.

47.4.14.5.1 Getting the SDMA Status

NOTE

Before executing any command that affects the SDMA (like `dmov` or `exec_once`), check that the SDMA is in debug mode.

Use the following snippet:

```
rstatus();           // read SDMA status until the SDMA is in debug mode
...
rstatus();
```

If the SDMA is not in debug mode, then a debug request must be generated. In this case, the SDMA enters debug mode at the end of the execution of the current instruction. Use this snippet:

```
debug_rqst(-);      // debug request
```

In the following sections, it is assumed that the SDMA was successfully put into debug mode.

47.4.14.5.2 Saving the Context

The first debug task is to save the SDMA context, which is the content of the eight general-purpose registers, the loop and PC-related registers, and the flags.

Functional Description

Use the general register GReg[1] as an intermediate register to export the entire context of the SDMA.

The following example shows how to save GReg[0], GReg[1], GReg[2] and GReg[3]. The sequence of commands used to export additional general registers is very similar to this.

Save GReg[0], GReg[1], GReg[2], and GReg[3]

```
GReg1_data = dmov(-); // the value exported is the content of
GReg[1]
exec_once("mov GReg1,GReg0"); // puts the content of GReg[0] into
GReg[1]
GReg0_data = dmov(-); // the value exported is the content of
GReg[0]
exec_once("mov GReg1, GReg2"); // puts the content of GReg[2] into
GReg[1]
GReg2_data = dmov(-); // the value exported is the content of
GReg[2]
exec_once("mov GReg1, GReg3"); // puts the content of GReg[3] into
GReg[1]
GReg3_data = dmov(-); // the value exported is the content of
GReg[3]
```

Get the value of the internal flags (SF, DF, T, and LM), of the loop related registers (EPC and SPC), and of the PC-related registers (PC and RPC). Use a done 5, which is the formatting instruction dedicated to the debug. This instruction formats the flags and the values contained in the registers. It also writes the resulting values into the channel context memory. It should not be used when entering debug from the IDLE state (for example, with no active channel script running on the SDMA), because it will update a channel context that may belong to any channel.

```
exec_once("done 5"); // formatting the value of flags and registers
```

At this point, the channel context should be up-to-date in memory, and debug operations should now be possible. However, the context can be exported with the following instructions:

Exporting the Context

```
dmov(ctx_base_addr); // loading GReg[1] with the channel
context_base_address
exec_once("ld GReg0, (GReg1,0)"); // get RPC-PC into GReg0
exec_once("ld GReg1, (GReg1,1)"); // get SPC-EPC into GReg1
Loop_data = dmov(-); // read back the value of Loop registers
exec_once("mov GReg1, GReg0"); // puts the PC info into GReg1
PC_data = dmov(-); // reads back the content of the PC registers
```

After this sequence of operations, the entire SDMA context is exported via the OnCE.

47.4.14.5.3 Restoring the Context

At this point in the operation, restore the context of the SDMA. It can be different from the original context located in memory, and the content previously saved into the debugging application via the OnCE.

The example found hereshows how it is possible to modify the current channel context.

Modifying the Current Channel Context

```

dmov(Loop_data); // put Loop former value into GReg[1]
exec_once("mov GReg0, GReg1"); // copy to GReg[0]
dmov(PC_data); // put PC former value into GReg[1]
exec_once("mov GReg2, GReg1"); // copy to GReg[2]
dmov(ctx_base_addr); // put channel context base address into
GReg[1]
exec_once("st GReg0, (GReg1,1)"); // restore Loop context
exec_once("st GReg2, (GReg1,0)"); // restore PC context

```

Once the context in memory is the desired context (with or without applying the previous instruction sequence), it can be restored to the *real* PC and loop registers in the SDMA core:

```

exec_once("cpShReg"); // restore flags and PC & loop related registers

```

After this command, the SDMA core PC, RPC, SPC, EPC registers, as well as the flags contain the same data as what is stored in the context RAM for the current channel.

The following example shows how to restore the context of general registers GReg[0], GReg[1], GReg[2] and GReg[3].

Restoring the General Register Context

```

dmov(GReg3_data); // put GReg[3] restore value in GReg[1]
exec_once("mov GReg3, GReg1"); // restore GReg[3]
dmov(GReg2_data); // put GReg[2] restore value in GReg[1]
exec_once("mov GReg2, GReg1"); // restore GReg[2]
dmov(GReg0_data); // put GReg[0] restore value in GReg[1]
exec_once("mov GReg0, GReg1"); // restore GReg[0]
dmov(GReg1_data); // restore GReg[1]

```

At this point, it is possible to restart the normal program execution.

NOTE

Every SDMA core general register value can be modified by a mov instruction, which makes modification of these registers easy during debug. Unfortunately, there is no such instruction as a mov to directly modify the contents of either PCU register or flag (PC, RPC, SPC, EPC, T, LM, SF, or DF). The cpShReg instruction is meant to provide a means for changing these register contents via the context memory.

47.4.14.5.4 Accessing the Memory

In the example shown here, it is assumed that the SDMA context is entirely saved. If true, it is permissible to modify the general purpose registers during debugging activity.

To perform a memory read access, the target address is stored via the OnCE in GReg[1], then the load instruction is executed on the SDMA (the data loaded from the memory overwrites the address contained in GReg[1]), and then the result value is read back via the OnCE.

```
macro READ:                dmov(target_addr);                // put the target
address in GReg[1]        exec_once("ld GReg1, (GReg1,0)");    // execute the
load instruction          res_data = dmov(-);                // exports the result
data value
```

For a memory write access, the target address is written in GReg[0], and the value to store is written in GReg[1]. Then the store instruction is executed on the SDMA.

```
macro WRITE:                dmov(target_addr);                // puts the
target address in GReg[1]  exec_once("mov GReg0, GReg1");    // puts the target
address in GReg[0]        dmov(target_data);                // puts the target
data in GReg[1]          exec_once("st GReg1, (GReg0,0)");    // performs the
store operation
```

This sequence is shown as an example; however, many other sequences are possible.

NOTE

This sequence of commands can also be applied to memory-mapped registers.

47.4.14.5.5 Resuming Program Execution

Before resuming program execution, it is assumed that the SDMA context is properly restored. There are two ways to restart the SDMA.

Start by executing the last instruction fetched before entering debug mode, as follows.

```
run_core(-);                // resume execution from where we stopped before
```

If necessary, restart the execution from a different address. In this case, use the `exec_core` command. The data field provided with this command must be the encoding of a jump instruction.

```
exec_core("jmp start_addr"); // rerun the SDMA from another address
```

In these two examples, the SDMA exits debug mode and keeps executing the code fetched from the memory.

47.4.14.5.6 Single Stepping in RAM

To execute a program step-by-step from the RAM, insert software breakpoints in the program flow at appropriate places so that the SDMA only executes one instruction before returning to debug mode.

First, read the next instruction to execute in the RAM. Then, depending on the value of this instruction, compute the address where a software breakpoint instruction should be inserted. The instruction at the corresponding address must be saved, and, the software breakpoint instruction is inserted. After restarting the SDMA, there is only one instruction executed before meeting the software breakpoint.

The following example shows the macro functions READ and WRITE, which correspond to the sequence of commands (described above) used to access the memory.

NOTE

The data read from the memory are 32-bit values, while the instructions are 16-bit values only. This is why it is best to only use addresses divided by two when accessing the memory.

READ and WRITE Macro Functions

```
next_instr = READ(run_addr/2);           // read the next instruction to execute
// the tool now has to compute the address where the breakpoint
// instruction should be inserted, this address is the "bkpt_addr"
instr_save = READ(bkpt_addr/2);         // save the instruction before
overwriting                               // store the bkpt instruction
STORE("bkpt instruction",bkpt_addr/2);
in memory
exec_core("jmp run_addr");              // rerun the SDMA
rstatus(-);                             // wait for the SDMA to enter debug mode
...
rstatus(-);
STORE(instr_save,bpkt_addr/2);          // restore the instruction
overwritten
```

In case of branched conditional instructions, a breakpoint instruction should be written at the two possible target addresses.

47.4.14.5.7 Single Stepping in ROM

No single-step mechanism is supported in ROM. The program code can be loaded in the RAM, where the single-step mechanism can be executed.

47.4.14.6 OnCE Event Detection Unit

The event detection unit watches signals from the data memory bus (DMBUS), which the SDMA core uses to access its RAM, ROM, and memory mapped registers.

Functional Description

A debug request is sent to the OnCE controller when user-defined conditions on address and/or data values are true.

Figure 47-13. Event Detection Unit

A counter, provided with the detection cell, is decreased after an event detection. A debug request is sent to the core only when the counter reaches the value of 0. It is possible to disable the use of the counter if a debug request has to be generated after each event detection.

The event cell is the basic block that supports hardware breakpoints on an address value and/or data values coming from the SDMA memory bus. The trigger condition that generates the debug request is a mixed condition based on those values.

The following figure shows the event cell architecture. The event cell contains the address (stored in the memory address register) and the data (stored in the memory data register) used during the last memory access. There are some user-defined reference values located in memory mapped registers—the event cell addresses, the event cell address mask, the event cell data, and the event cell data mask. These registers are accessed by standard load/store instructions just like regular memory locations.

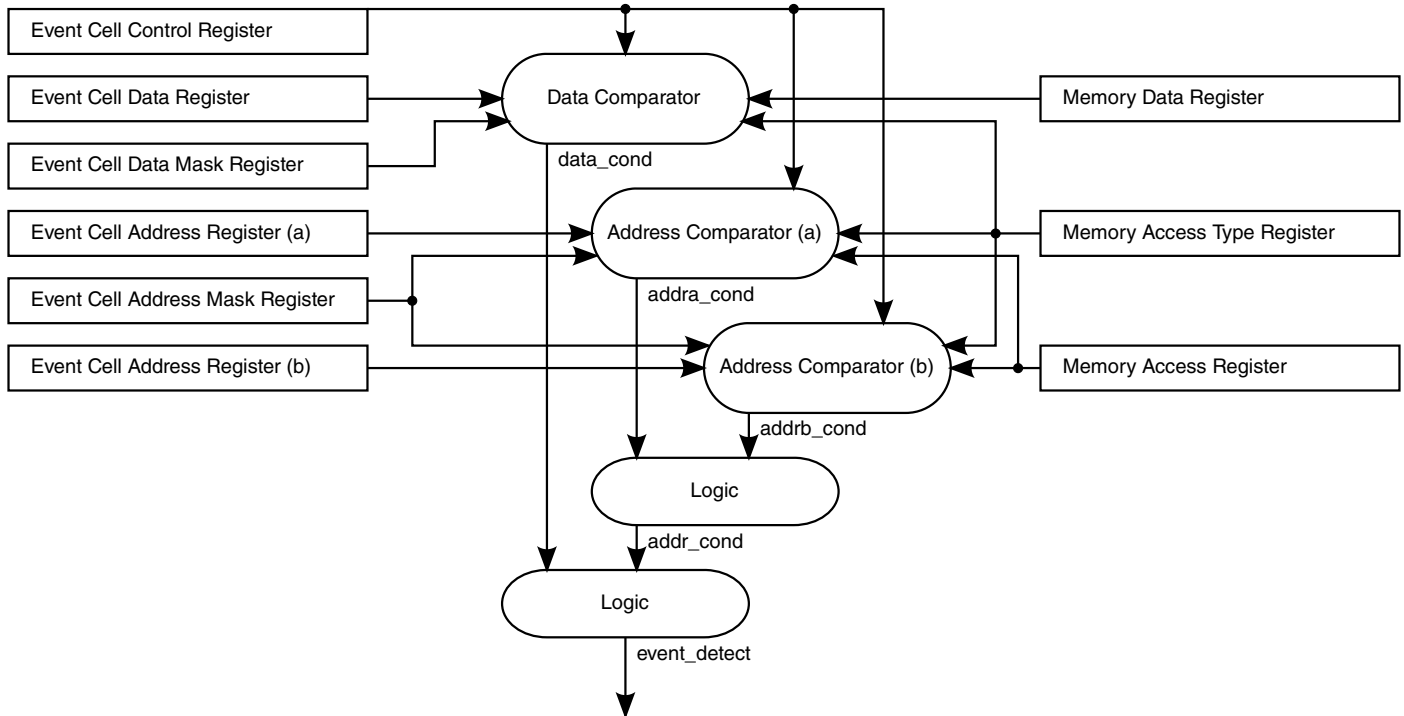

Figure 47-14. Event Cell Architecture

To define a memory breakpoint, three conditions are taken into account: The first two conditions are comparisons of the current memory address with user-defined reference addresses (these conditions are called addressA and addressB). The third condition consists of a comparison between the data received on the DMBUS and a user-defined reference data (this condition is called data). An intermediate address condition is set to express a dependency between addressA and addressB conditions.

47.4.14.7 Clock Gating and Reset

This section details how to use the clocks and handle the reset signals.

47.4.14.7.1 Clocks

Because the SDMA uses clock gating to save power, it is necessary to disable the clock gating and force the clocks to be enabled when using the OnCE.

When the OnCE is accessed through its JTAG interface, clock gating must be disabled outside the SDMA via a dedicated SDMA input port `clk_gating_off`. The reason why detection is not performed automatically by the SDMA internal hardware is that it would cost power to monitor activity on the JTAG interface.

When the OnCE is accessed through the ARM platform Control interface, clock gating is automatically turned off. This is done when bit 0 of the ONCE_ENB register (see [OnCE Enable \(SDMAARM_ONCE_ENB\)](#)) is set. A write access to this register is possible even when the OnCE clock is not running. If the ARM platform access is used, the bit in the ONCE_ENB register must be set before any attempt to access any other OnCE register.

47.4.14.7.2 Resets

The OnCE reset is different from the SDMA main reset.

Normally, activating the SDMA reset while keeping the OnCE reset inactive (when possible) enables you to reset the core without having to reprogram the OnCE.

47.4.14.8 Real Time Features

To rebuild the skeleton of a program execution, it is necessary to store the addresses of the program instructions where jumps are taken: A trace buffer is therefore provided. A real time buffer has also been added to receive data values written during a program execution.

The content of this register may be exported through JTAG ports without stopping the core.

47.4.14.8.1 Trace Buffer

The Trace Buffer is a 32-stage buffer that contains appropriate information to identify the 32 last changes of flow detected during a program execution.

The following figure shows an overview of the Trace Buffer.

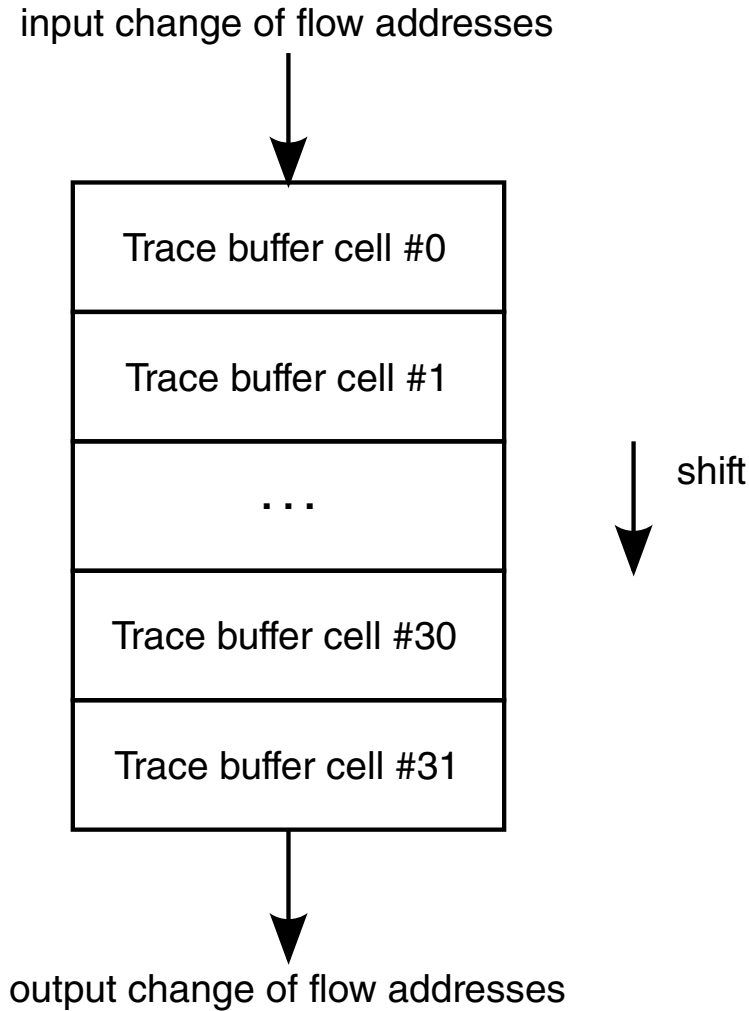

Figure 47-15. Trace Buffer

Each cell of the trace buffer contains two reference addresses and a flag. The flag is set when the addresses stored in the cell correspond to a valid change of flow; otherwise, the flag is cleared. The three most significant bits are unused.

After every change of flow detection, the address of current instruction and the address of the target instruction are stored at the top of the Trace Buffer (cell #0). The flag in the cell is set to indicate that a valid change of flow was detected. Former cell values are shifted one level down. The Trace Buffer contains the 32 last changes of flow. All the flags are reset on a software or a hardware reset, and after each transition from debug mode to user mode.

Functional Description

A memory mapped register of SDMA core, the Trace Buffer register (TB), is provided to read the content of the Trace Buffer. This operation should be done in debug mode. Performing a read access to the Trace Buffer register returns the content of the bottom of the Trace Buffer (cell #31). After every read access, the trace buffer is shifted one level down, and the flag at the top of the trace buffer is cleared.

A typical OnCE command sequence that retrieves the oldest change-of-flow information is as follows:

```
exec_once("mov r1, TB"); // stores the oldest change-of-flow in
GReg1
dmov(-); // retrieves GReg1 contents
```

This sequence requires the SDMA to be put in debug mode.

47.4.14.8.2 Real Time Buffer

The Real Time Buffer register (RTB) is a memory mapped register that can be accessed as a regular memory location by the SDMA core during program execution. This register is located in the OnCE.

Executing an `rbuffer` command (see [The OnCE Controller](#) for further details) exports the content of this register through JTAG ports.

When a write access is performed at the memory location corresponding to the RTB, the receive flag (for example, the RCV bit) is set in the OnCE Status Register (OSR). This flag is cleared at the end of the execution of a `rbuffer` command.

NOTE

Every write access to the RTB memory location updates the RTB register even if the RCV flag is set. The RTB is cleared on a JTAG reset.

47.4.14.8.3 Emulation Pin

The `debug_matched_event` emulation pin reflects the matching condition status detected by the Event Detection Unit.

Since it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

47.4.14.8.4 Real-Time Debug Outputs

The table found here shows the debug signals that are available at the SDMA boundaries. Their availability at chip boundaries depends on the project.

Table 47-41. Real-Time Debug Output Pins

Pin	Description
debug_core_state[3:0]	<p>The core_state bits reflect the state of the SDMA core.</p> <ul style="list-style-type: none"> • The "Program" state is the usual instruction execution cycle. • The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. • The "Debug" state means the SDMA is in debug mode. • The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In "Sleep" modes, no script is running (this is the core idle state); the "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 is executed (boot operation). • The "in Sleep" states are the same as above except they do not have any corresponding channel: they are used when entering debug mode after reset; the reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. <p>0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Context Switch Saving Channel 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change of Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Context Switch Restoring Channel</p>
debug_yield	<p>Pulse that is active when a yield (done 0) or a yieldge (done 1) instruction is executed.</p> <p>0 - 1 yield/yieldge executed</p>
debug_core_run	<p>Active when the SDMA core is executing instructions.</p> <p>0 Debug or sleep mode</p>

Table continues on the next page...

Table 47-41. Real-Time Debug Output Pins (continued)

Pin	Description
	1 Run mode
debug_event_channel_sel	Indicates if debug_event_channel displays current channel or last received event 0- debug_event_channel[5:0] gives the number of the current channel 1- debug_event_channel[5:0] gives the number of the last received event
debug_event_channel[5:0]	Gives the number of any DMA request as soon as it is received or the number of the current channel. The value of debug_event_channel_sel indicates if debug_event_channel displays the current channel or last received event. The signal debug_event_channel_sel must be observed to determine what information is provided on debug_event_chanel at any given time.
debug_pc[13:0]	Program Counter value; it has a meaning when the core is in run mode.
debug_mode	Set when the core is in debug. 0 - 1 Core is in debug
debug_bus_error	Set when an error was received during a load or a store (ld, st, ldf, or stf instruction) and registered in SF or DF flag. 0 No error during last load/store 1 Error during last load/store
debug_bus_device[4:0]	Indicates the device or functional unit that is accessed by the current instruction. The debug_bus_device output is always valid when in sleep mode, debug mode, or executing any instruction that does not access the functional units or the memory mapped devices, "no access" is output. 0 No access 1 MSA 2 MDA 3 MD 4 MS 5 PSA 6 PDA 7 PD 8 PS 9 RESERVED 10 RESERVED 11 RESERVED 12 RESERVED 13 CA 14 CS 15 Reserved 16 Memory (RAM or ROM) 17 Memory mapped register

Table continues on the next page...

Table 47-41. Real-Time Debug Output Pins (continued)

Pin	Description
	18 Peripheral #1 19 Peripheral #2 20 Peripheral #3 21 Peripheral #4 22 Peripheral #5 23 Peripheral #6 24 Peripheral #7 25 Peripheral #8 26 Peripheral #9 27 Peripheral #10 28 Peripheral #11 29 Peripheral #12 30 Peripheral #13 31 Peripheral #14
debug_bus_rwb	Indicates the direction of the access given by debug_bus_device 0 Write access (st or stf) 1 Read access (ld or ldf)
debug_matched_dmbus	Pulse indicating the OnCE event detection unit has detected a match on the data bus during an access to memory (RAM or ROM), a memory mapped register or a peripheral that is hooked to the SDMA. 0 - 1 data bus match detected
debug_rtbuffer_write	Pulse indicating when the real-time buffer is written by the core. 0 - 1 RTB was modified
debug_evt_chn_lines[7:0]	Eight lines that generate short pulses when DMA requests are received or channels are (re)started. Every line is controlled through two parameters defined in registers Cross-Trigger Events Configuration Register 1 (SDMAARM_XTRIG_CONF1) (as described in SDMAARM). The following two parameters are available for every line: <ul style="list-style-type: none"> • CNF-Indicates what is monitored on the line: 0 for a channel start, 1 for a DMA request reception • NUM[5:0]-Gives the number of the DMA request or channel to monitor

The `matched_event` emulation pin reflects the matching condition status detected by the Event Detection Unit. Because it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

All real-time debug outputs are disabled by default (for example, they are stuck to 0) to avoid power consumption when they are not used. They are enabled when bit 11 (RTDOBS) of the [Configuration Register \(SDMAARM_CONFIG\)](#) is set. Signals provided to the system JTAG controller for SDMA debug mode status will also be enabled when the *clk_gating_off* input is asserted.

47.5 Instruction Set

47.5.1 Instruction Encoding

This section presents a short summary of the instruction codes. All context switch instructions are listed for information only; they cannot function properly out of the context switch routine.

```

x...x - don't care

rrr - destination/source general register

sss - additional source general register

bbb - general register used as address base register

dddd - address displacement

nnnn - bit number
uuuuuuu - function unit command bits

pppppppp - branch displacement (signed)

iiiiiii - 8-bit immediate

jjj - control bit to clear

ff - flag to clear

47.5.2 SDMA Instruction Set

This section describes all the useful instructions from the SDMA set.

Table 47-42. SDMA Instruction List

Instruction	Description	Page
ADD	Addition	ADD (Addition)
ADDI	Add with Immediate Value	ADDI (Add with Immediate Value)
AND	Logical AND	AND (Logical AND)
ANDI	Logical AND with Immediate Value	ANDI (Logical AND with Immediate Value)
ANDN	Logical AND NOT	ANDN (Logical AND NOT)
ANDNI	Logical AND with Negated Immediate Value	ANDNI (Logical AND with Negated Immediate Value)
ASR1	Arithmetic Shift Right by 1 Bit	ASR1 (Arithmetic Shift Right by 1 Bit)
BCLRI	Bit Clear Immediate	BCLRI1 (Bit Clear Immediate)
BDF	Conditional Branch if Destination Fault	BDF (Conditional Branch if Destination Fault)
BF	Conditional Branch if False	Functional Units Programming Model
BSETI	Bit Set Immediate	BSETI (Bit Set Immediate)
BSF	Conditional Branch if Source Fault	BSF (Conditional Branch if Source Fault)
BT	Conditional Branch if True	BT (Conditional Branch if True)
BTSTI	Bit Test immediate	BTSTI (Bit Test immediate)
CLRF	Clear ARM platform flags	CLRF (Clear ARM platform flags)
CMPEQ	Compare for Equal	CMPEQ (Compare for Equal)
CMPEQI	Compare with Immediate for Equal	CMPEQI (Compare with Immediate for Equal)
CMPHS	Compare for Higher or Same	CMPHS (Compare for Higher or Same)
CMPLT	Compare for Less Than	CMPLT (Compare for Less Than)
cpShReg	Update Context of PCU Registers and Flags	cpShReg (Update Context of PCU Registers and Flag)
DONE	DONE, Yield	DONE (DONE, Yield)
ILLEGAL	ILLEGAL Instruction	ILLEGAL (ILLEGAL Instruction)
JMP	Unconditional Jump Immediate	JMP (Unconditional Jump Immediate)
JMPR	Unconditional Jump	JMPR (Unconditional Jump)
JSR	Unconditional Jump to Subroutine Immediate	JSR (Unconditional Jump to Subroutine Immediate)
JSRR	Unconditional Jump to Subroutine	JSRR (Unconditional Jump to Subroutine)
LD	Load Register	LD (Load Register)
LDF	Load Register from Functional Unit	LDF (Load Register from Functional Unit)

Table continues on the next page...

**Table 47-42. SDMA Instruction List
(continued)**

Instruction	Description	Page
LDI	Load Register with Immediate Value	LDI (Load Register with Immediate Value)
LDRPC	Load from RPC to Register	LDRPC (Load from RPC to Register)
LOOP	Hardware Loop	LOOP (Hardware Loop)
LSL1	Logical Shift Left by 1 Bit	LSL1 (Logical Shift Left by 1 Bit)
LSR1	Logical Shift Right by 1 Bit	LSR1 (Logical Shift Right by 1 Bit)
MOV	Logical Move	MOV (Logical Move)
NOTIFY	Notify to ARM platform	NOTIFY (Notify to ARM platform)
OR	Logical OR	OR (Logical OR)
ORI	Logical OR with Immediate Value	ORI (Logical OR with Immediate Value)
RET	Return from Subroutine	RET (Return from Subroutine)
REVB	Reverse Byte Order	REVB (Reverse Byte Order)
REVBLO	Reverse Low Order Bytes	Reverse Low Order Bytes(REVBLO)
ROR1	Rotate Right by 1 Bit	ROR1 (Rotate Right by 1 Bit)
RORB	Rotate Right by 1 Byte	RORB (Rotate Right by 1 Byte)
SOFTBKPT	Software Breakpoint	SOFTBKPT (Software Breakpoint)
ST	Store Register	ST (Store Register)
STF	Store Register in Functional Unit	STF (Store Register in Functional Unit)
SUB	Subtract	SUB (Subtract)
SUBI	Subtract with Immediate	SUBI (Subtract with Immediate)
TST	Test with Zero	TST (Test with Zero)
TSTI	Test Immediate	TSTI (Test Immediate)
XOR	Logical Exclusive OR	XOR (Logical Exclusive OR)
XORI	Exclusive OR with Immediate	XORI (Exclusive OR with Immediate)

47.5.2.1 ADD (Addition)

Operation:

$$\text{GReg}[r] \leftarrow \text{GReg}[s] + \text{GReg}[r]$$

$$T \leftarrow (\text{GReg}[r] == 0)$$

Assembler:

Syntax: `add r,s`

Example: `add 0,3`

ADD GReg[3] and GReg[0] and store the result in GReg[0]

CPU Flags: T

Instruction Set

Cycles: 1

Description: Performs the ADDition of the source general register s and the destination general register r , and stores the result in the destination general register r . The T flag is set if the result of the operation is 0. It is cleared if the result is not 0.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.2 ADDI (Add with Immediate Value)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[r] + \text{immediate}$

$T \leftarrow (\text{GReg}[r] == 0)$

Assembler:

Syntax: `addi r,immediate`

Example: `add 6,112`

ADD GReg[6] and decimal value 112 and store the result in GReg[6]

CPU Flags: T

Cycles: 1

Description: Adds a 0-extended immediate value to a general register; stores the result in the general register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

47.5.2.3 AND (Logical AND)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[s] \ \& \ \text{GReg}[r]$

Assembler:

Syntax: `and r,s`

Example: `and 1,2`

AND GReg[1] and GReg[2] and store the result in GReg[1]

Instruction Set

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.4 ANDI (Logical AND with Immediate Value)

Operation:

$GReg[r] \leftarrow GReg[r] \& \text{immediate}$

Assembler:

Syntax: `andi r,immediate`

Example: `andi 7,45`

AND GReg[7] and decimal value 45 and store the result in GReg[7]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between a 0-extended immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

47.5.2.5 ANDN (Logical AND NOT)**Operation:**

GReg[r] ← ~GReg[s] & GReg[r]

Assembler:

Syntax: andn r, s

Example: andn 3, 4

AND GReg[3] and NOT GReg[4] (bit inverted) and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Instruction Set

Description: Performs the AND of the negation of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format:

Table 47-43. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	0	s	s	s

Instruction Fields:

rrr /sss - destination register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.6 ANDNI (Logical AND with Negated Immediate Value)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[r] \& \sim\text{immediate}$

Assembler:

Syntax: `andni r,immediate`

Example: `andni 0,2`

AND GReg[0] and decimal value -3 (inverted 32-bit value 2) and store the result in GReg[0]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between the negation of a 0-extended 8-bit immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

47.5.2.7 ASR1 (Arithmetic Shift Right by 1 Bit)**Operation:**

$$\text{GReg}[r] : \{b_{31}, b_{30}, \dots, b_1, b_0\} \leftarrow \text{GReg}[r] : \{b_{31}, b_{31}, b_{30}, \dots, b_1\}$$
Assembler:Syntax: `asr1 r`Example: `asr1 3`

divide by 2 the signed value of GReg[3] and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Instruction Set

Description: Shift the bits of any general register to the right and keep the same sign: The left bit (bit 31) is kept untouched.

Instruction Format:

Table 47-44. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.8 BCLRI1 (Bit Clear Immediate)

Operation:

$\text{GReg}[r] : \{b_{31}, \dots, b_{(i+1)}, 0, b_{(i-1)}, \dots, b_0\} \leftarrow \text{GReg}[r] : \{b_{31}, \dots, b_{(i+1)}, b_{(i)}, b_{(i-1)}, \dots, b_0\}$

Assembler:

Syntax: `bclri r,i`

Example: `bclri 1,12`

clear bit 12 in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Clear the bit of register r specified by the 5-bit immediate field

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
----	----	----	----	----	----	---	---	---	---	---	---	---	---	---	---

00000 - 0

00001 - 1

...

11110 - 30

11111 - 31

47.5.2.9 BDF (Conditional Branch if Destination Fault)

Operation:

if (DF == 1) PC ← PC + 1 + displacement else PC ← PC + 1

Assembler:

Syntax: bdf label

Example: bdf LLL

Jump to LLL if DF is set, or go to the next instruction if DF is cleared; the displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: If flag DF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag DF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Set

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	1	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)
```

47.5.2.10 BF (Conditional Branch if False)

Operation:

```
if (T == 0)
PC ← PC + 1 + displacement
else
PC ← PC + 1
```

Assembler:

Syntax: bf label

Example: bf LLL

Jump to LLL if T is cleared, or go to the next instruction if T is set. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is cleared, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is set, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	0	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```

00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)

```

47.5.2.11 BSETI (Bit Set Immediate)

Operation:

$$GReg[r] : \{b31, \dots, b(i+1), 1, b(i-1), \dots, b0\} \leftarrow GReg[r] : \{b31, \dots, b(i+1), b(i), b(i-1), \dots, b0\}$$

Assembler:

Syntax: `bseti r,i`

Example: `bseti 6,5`

Set bit 5 in GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Sets bit number *i* in the selected General Register.

Instruction Format

Instruction Set

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	0	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiii - bit number field:

00000 - 0

00001 - 1

...

11110 - 30

11111 - 31

47.5.2.12 BSF (Conditional Branch if Source Fault)

Operation:

if (SF == 1) PC ← PC + 1 + displacement else PC ← PC + 1

Assembler:

Syntax: `bsf label`

Example: `bsf LLL`

Jump to LLL if SF is set, or go to the next instruction if SF is cleared. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag SF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag SF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	0	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)
```

47.5.2.13 BT (Conditional Branch if True)

Operation

```
if (T == 1)
PC ← PC + 1 + displacement
else
PC ← PC + 1
```

Assembler

```
Syntax: bt label

bt LLL
```

Jump to LLL if T is set, or go to the next instruction if T is cleared. The displacement value is calculated by the assembler.

Instruction Set

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	1	p	p	p	p	p	p	p	p

pppppppp - signed displacement field:

```
00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)
```

47.5.2.14 BTSTI (Bit Test immediate)

Operation:

$T \leftarrow \text{GReg}[r]:b(i)$

Assembler:

Syntax: `btsti r,i`

Example: `btsti 2,29`

Test bit 29 in GReg[2] and copy its value in flag T

CPU flags: T

Cycles: 1

Description: T is loaded with the value of bit number i from the selected general register.

Instruction Format:

Table 47-45. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	1	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

0000 - 0

0001 - 1

...

11110 - 30

11111 - 31

47.5.2.15 CLRF (Clear ARM platform flags)

Operation:

```
if (ff%2 == 0)
```

```
SF ← 0
```

```
if (ff/2 == 0)
```

```
DF ← 0
```

Assembler:

```
Syntax: clrf ff
```

```
Example: clrf 2
```

Instruction Set

Clear flag SF and keep flag DF unchanged

CPU Flags: SF, DF

Cycles: 1

Description: Clears a selection of the ARM platform fault flags: SF, DF, both SF and DF or none can be cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	f	f	0	0	0	0	0	1	1	1

Instruction Fields:

ff - flags field:

00 - clear SF and clear DF

01 - clear DF

10 - clear

SF 11 - no clear

47.5.2.16 CMPEQ (Compare for Equal)

Operation:

$T \leftarrow (GReg[s] == GReg[r])$

Assembler:

Syntax: `cmpeq r,s`

Example: `cmpeq 7,5`

Compare GReg[7] and GReg[5] and set flag T if they are equal

CPU flags: T

Cycles: 1

Description: Subtracts the destination general register *r* from the source general register *s*, and sets T if the result is 0, clears T if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.17 CMPEQI (Compare with Immediate for Equal)**Operation:** $T \leftarrow (\text{GReg}[r] == \text{immediate})$ **Assembler:**Syntax: `cmpeqi r,immediate`Example: `cmpeqi 2,13`

Compare GReg[2] and decimal value 13 and set flag T if they are equal

CPU Flags: T

Cycles: 1

Description: Subtracts the 0-extended 8-bit immediate value from the general register, and sets T if the result is 0, clears T if the result is not 0. The immediate value is the low-order byte of the instruction.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - destination register field:

000 - GReg[0]

Instruction Set

001 - GReg[1]
010 - GReg[2]
011 - GReg[3]
100 - GReg[4]
101 - GReg[5]
110 - GReg[6]
111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0
00000001 - 1
...
11111110 - 254
11111111 - 255

47.5.2.18 CMPHS (Compare for Higher or Same)

Operation:

$T \leftarrow (\text{GReg}[r] \geq \text{GReg}[s])$

Assembler:

Syntax: `cmphs r,s`

Example: `cmphs 0,1`

Compare GReg[0] and GReg[1] and set flag T if GReg[0] is higher than or equal to GReg[1]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is higher than or equal to the source general register *s*, clears T otherwise. The comparison is unsigned.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	1	s	s	s

Instruction Fields:**rrr / sss - register field:**

000 - GReg[0]
 001 - GReg[1]
 010 - GReg[2]
 011 - GReg[3]
 100 - GReg[4]
 101 - GReg[5]
 110 - GReg[6]
 111 - GReg[7]

47.5.2.19 CMPLT (Compare for Less Than)**Operation:**

$$T \leftarrow (\text{GReg}[r] < \text{GReg}[s])$$
Assembler:

Syntax: `cmplt r,s`

Example: `cmplt 7,4`

Compare GReg[7] and GReg[4] and set flag T if GReg[7] is lower than GReg[4]

CPU Flags: T**Cycles: 1**

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is lower than the source general register *s*, clears T otherwise. The comparison is signed.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	0	s	s	s

rrr / sss - register field:

000 - GReg[0]
 001 - GReg[1]
 010 - GReg[2]

Instruction Set

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.20 cpShReg (Update Context of PCU Registers and Flag)

Assembler:

Syntax: cpShReg

CPU Flags: none

Cycles: 1

Description: SF, RPC, T, PC,LM, EPC, DF, and SPC registers are updated according to the value of their corresponding bits in the context memory. This instruction must only be used in debug mode via the OnCE. It reverses the done 5 operation.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	0	1	1	1	0	0	0	1	0

47.5.2.21 DONE (DONE, Yield)

Operation:

```
if (jjj&6 == 2) HE[CCR] ← 0
```

```
if (jjj == 3) HI[CCR] ← 1
```

```
if (jjj == 4) EP[CCR] ← 0
```

```
if ((jjj == 0) && (NCP > CCP)) CCR ← NCR
```

```
else if ((jjj == 1) && (NCP >= CCP))
```

```
CCR ← NCR
```

```
else
```

```
CCR ← NCR
```

(CCR stands for Current Channel Register; NCR stands for Next Channel Register)

Assembler:

Syntax: done jjj

Example: done 3

Clear HE bit for the current channel, send an interrupt to the ARM platform for the current channel and reschedule.

CPU Flags: Unaffected

Cycles: Variable if a context switch is done, 1 otherwise

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required. Sends an interrupt to the corresponding ARM platform by setting the appropriate flag, if required (HI for the corresponding channel number). Reschedules according to the mode and the NCP (Next Channel Priority) and CCP (Current Channel Priority) values. According to the scheduling decision, the NCR (Next Channel Register) is copied to the CCR (Current Channel Register) and channel contexts are switched. If several channels with the same highest priority are pending, they are ordered by their number from 31 down to 0. The higher number is selected (for example, channel 26 is selected if channels 3, 12, 14, and 26 with the same highest priority are pending). If no flag is modified, the reschedule can allow the replacement of the current channel by another channel with a priority strictly greater than the current channel priority (yield). Or, it can allow the replacement of the current channel by another channel with a priority greater than or equal to the current channel priority (yieldge). In the latter case, the selected channel will always be the first one with the same priority, starting from channel number 31 down to channel 0 (the current channel does not belong to the set of selectable channels).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	0

jjj - Channel Flags field:

000 - No channel flags affected: Reschedule only if the next channel priority is greater than current channel priority (yield)

001 - No channel flags affected: Reschedule only if the next channel priority is greater than or equal to the current channel priority (yieldge)

010 - Clear HE for the current channel and reschedule 011 - Clear HE, set HI for the current channel and reschedule 100 - Clear EP for the current channel and reschedule

101 - Reserved for debug to copy relevant registers into context memory

110 - RESERVED

111 - RESERVED

For the scheduling rules, refer to [Scheduler Functional Description](#). Every possible done instruction is further described as follows:

- done 0/yield is executed by a channel script when it accepts preemption by a higher priority channel;
- done 1/yieldge is executed by a channel script when it accepts preemption by a higher priority channel and it also accepts a roll-up with other channels that have the same priority;
- done 2 is executed by a channel script that was triggered by a ARM platform start via the [Channel Start \(SDMAARM_HSTART\)](#) register, when its task is completed and it requires termination;
- done 3 is executed by a channel script that was triggered by a ARM platform start via the [Channel Start \(SDMAARM_HSTART\)](#) register, when its task is completed, it requires termination and it needs to trigger an interrupt to the ARM platform upon closure;
- done 4 is executed by a channel script that was triggered by a DMA request, when its task is completed and it requires termination;
- done 5 is used in debug mode only; it copies the PCU registers and flags to the context memory of the current channel;

47.5.2.22 ILLEGAL (ILLEGAL Instruction)

Operation:

PC ← 0001

Assembler:

Syntax: illegal

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the Illegal instruction routine located at address 0001. All unauthorized instructions result in an Illegal instruction behavior; however, the ILLEGAL instruction must be used to guarantee software compatibility with future versions of the SDMA.

Instruction Format

Table 47-46. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1

47.5.2.23 JMP (Unconditional Jump Immediate)

Operation:

PC \leftarrow absolute_address

Assembler:

Syntax: jmp label

Example: jmp LLL

The assembler translates the label to the exact address

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	a	a	a	a	a	a	a	a	a	a	a	a	a	a

aaaaaaaaaaaaaaaa - address field:

00000000000000 - 0

000000000000001 - 1

...

111111111111110 - 16382

111111111111111 - 16383

47.5.2.24 JMPR (Unconditional Jump)

Operation:

PC \leftarrow GReg[r]

Instruction Set

Assembler:

Syntax: `jmp r`

Example: `jmp 0`

Jump to address stored in GReg[0]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the absolute address contained in a General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.25 JSR (Unconditional Jump to Subroutine Immediate)

Operation:

$RPC \leftarrow PC + 1$

$PC \leftarrow \text{absolute_address}$

Assembler:

Syntax: `jsr r`

Example: `jsr LLL`

Jumps to subroutine starting at LLL; the assembler translates the label to exact address

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine located at the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	a	a	a	a	a	a	a	a	a	a	a	a	a	a

aaaaaaaaaaaaaaaa - address field:

0000000000000000 - 0

0000000000000001 - 1

...

1111111111111110 - 16382

1111111111111111 - 16383

47.5.2.26 JSRR (Unconditional Jump to Subroutine)

Operation:

$RPC \leftarrow PC + 1$

$PC \leftarrow GReg[r]$

Assembler:

Syntax: jsrr r

Example: jsrr 5

Jumps to subroutine located at address stored in GReg[5]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine at address contained in a General Register

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	1

Instruction Fields:**rrr - register field:**

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.27 LD (Load Register)

Operation: $\text{GReg}[r] \leftarrow [\text{GReg}[b] + \text{displacement}]$

if (transfer_error)

SF \leftarrow 1

else

SF \leftarrow 0**Assembler:**

Syntax: ld r, (b, displacement)

Example: ld 1, (2, 23)

Loads data into GReg[1]; the data is located at address obtained by adding decimal value 23 to GReg[2]

CPU Flags: SF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to fetch on the DM bus. The data received from the bus is stored in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	0	r	r	r	d	d	d	d	d	b	b	b

rrr / bbb - register field:

000 - GReg[0]

001 - GReg[1]

...

111 - GReg[7]

dddd - displacement value:

00000 - 0

00001 - 1

...

11111 - 31

47.5.2.28 LDF (Load Register from Functional Unit)

Operation:

GReg[r] ← [fu_address]

if (transfer_error)

SF ← 1

else

SF ← 0

fu_address is an 8-bit field and depends on addressed functional unit

Assembler:

Syntax: ldf r, fu_address

Example: ldf 0, 13

Loads data coming from the Burst DMA register MD into GReg[0]; it is a 32-bit access with no prefetch

CPU Flags: SF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Instruction Set

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and stores the data received from the bus in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	0	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the LDF instruction usage with each functional unit:

- [Burst DMA Read \(ldf\)](#) for Burst DMA
- [Peripheral DMA Read \(ldf\)-Read Mode](#) for Peripheral DMA

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

ffffff - functional unit source register and action (unspecified values are reserved):

00000000 - MSA

00000100 - MDA

00001001 - MD byte

00001010 - MD halfword

00001011 - MD word

00001100 - MS

00101001 - MD byte - prefetch

00101010 - MD halfword - prefetch

00101011 - MD word - prefetch

01000000 - DSA

11000000 - PSA
 11001000 - PD
 11010000 - PDA
 11011000 - PD in copy mode (rrr contents are lost)
 11101000 - PD - prefetch next data
 11111111 - PS

47.5.2.29 LDI (Load Register with Immediate Value)

Operation:

GReg[r] ← immediate

Assembler:

Syntax: ldi r,immediate

Example: ldi 6,1

loads decimal value 1 into GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Stores a 0-extended immediate value in a General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]
 001 - GReg[1]
 010 - GReg[2]
 011 - GReg[3]
 100 - GReg[4]
 101 - GReg[5]

Instruction Set

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

47.5.2.30 LDRPC (Load from RPC to Register)

Operation:

GReg[r] ← RPC

Assembler:

Syntax: `ldrpc r`

Example: `ldrpc 3`

copies RPC to GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Stores the contents of the RPC in a General Register. That instruction may be used to have more than one level of subroutines.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	1	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]
 110 - GReg[6]
 111 - GReg[7]

47.5.2.31 LOOP (Hardware Loop)

Operation:

```

if (ff%2 == 0)
    SF ← 0
if (ff/2 == 0)
    DF ← 0
if ((GReg[0] == 0) || (SF == 1) || (DF == 1))
    PC ← PC + loop_size + 1
else
    {
        SPC ← PC + 1
        EPC ← PC + loop_size + 1
        LM ← 1
        PC ← PC + 1
    }

```

during every instruction execution in the loop:

```

if ((SF == 1) || (DF == 1))
    {
        LM ← 0
        PC ← EPC
    }
else if ((PC + 1) == EPC)
    {
        GReg[0] ← GReg[0] - 1
        if (GReg[0] == 0)
            {
                LM ← 0
                PC ← EPC
            }
    }

```

Instruction Set

```
    }  
    else  
        PC ← SPC  
    }  
else  
    PC ← nextPC(instruction)
```

after the execution of the last instruction of the loop body:

```
if (GReg[0] == 0)  
    T ← 1  
else  
    T ← 0
```

Assembler:

Syntax: `loop n{,ff}`

Example: `loop 3,1`

Executes GReg[0] times the instructions comprised between PC+1 and PC+3 (included); ff=1 clears the DF flag before starting the loop. When omitted, the ff field is set to 0 (clearing both SF and DF).

CPU Flags: LM[1:0], T

Cycles: 2 when the loop count (GReg[0]) is 0 or SF or DF is set at loop start, 1+1 when the loop starts but exits abnormally (SF or DF set inside the loop which adds 1 cycle to the offending load or store to jump to EPC), 1 when the loop is executed normally

Description: The loop instruction executes a sequence of instructions several times. The number of times is given by the contents of GReg[0], the loop counter. SDMA will jump to the first instruction after the end of the loop if the value in GReg[0] is 0. Otherwise the SDMA enters loop mode. It sets the most significant bit of the LM flag that will only be reset once the last instruction of the last loop is executed. The instructions in the loop are executed GReg[0] times. The management of fault flags (SF and DF) is as follows. When entering the hardware loop, SF and DF can be cleared according to the ff field of the instruction. After that operation, if any flag is still set the loop will not be executed. The SDMA will jump to the first instruction after the end of the loop without entering loop mode. During the execution of the loop, if any fault flag is set by a LD, LDF, ST, or STF instruction, the SDMA will immediately exit loop mode and jump to the first instruction after the end of the loop. In that case, GReg0 is not decremented for that last piece of the loop body execution (even if the SF or DF flag is set at the last instruction of the loop body). The T flag reflects the state of GReg[0] after the end of the loop, which is an indicator of the complete execution of the loop. If the loop exited because of an error (SF

or DF set), GReg[0] will not be 0 at the end of the loop, hence T will be cleared. If the loop executes without fault, GReg[0] will be 0 at the end of the loop, hence T will be set. The boundary case when a source or destination fault occurs at the last instruction of the last loop is considered as an anticipated exit of the loop, which causes the T flag to be cleared. If the last instruction executed before leaving the hardware loop also tries to modify the T flag, the flag is updated according to the value of GReg[0], NOT according to the result of the last executed instruction.

Limitations:

1. 1. Jump instructions (JMP, JMPR, JSR, JSRR, BF, BT, BSF, BDF) are not allowed inside the hardware loop.
2. 2. GReg[0] cannot be written to inside the hardware loop (it can be read).
3. 3. The empty loop (0 instruction in the body) is forbidden.
4. 4. If GReg[0] == 0 at the start of the loop, which causes a jump to EPC, the T flag is not updated.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	0	f	f	n	n	n	n	n	n	n	n

Instruction Fields:

ff - flags field:

00 - clear SF and clear DF

01 - clear DF

10 - clear SF

11 - no clear

nnnnnnnn - loop size

00000000 - empty loop: forbidden value

00000001 - 1 instruction in the loop

00000010 - 2 instructions in the loop

...

11111111 - 255 instructions in the loop

47.5.2.32 LSL1 (Logical Shift Left by 1 Bit)

Operation:

Instruction Set

$\text{GReg}[r] : \{b30, \dots, b1, b0, 0\} \leftarrow \text{GReg}[r] : \{b31, b30, \dots, b1, b0\}$

Assembler:

Syntax: `lsl1 r`

Example: `lsl1 2`

multiplies by 2 the value in `GReg[2]`

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the left. The right bit (bit 0) is set to 0. No overflow is detected by the hardware.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	1

Instruction Fields:

rrr - register field:

000 - `GReg[0]`

001 - `GReg[1]`

010 - `GReg[2]`

011 - `GReg[3]`

100 - `GReg[4]`

101 - `GReg[5]`

110 - `GReg[6]`

111 - `GReg[7]`

47.5.2.33 LSR1 (Logical Shift Right by 1 Bit)

Operation:

$\text{GReg}[r] : \{0, b31, b30, \dots, b1\} \leftarrow \text{GReg}[r] : \{b31, b30, \dots, b1, b0\}$

Assembler:

Syntax: `lsr1 r`

Example: `lsr1 4`

divides by 2 the unsigned value contained in `GReg[4]`

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the right. The left bit (bit 31) is set to 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	1

Instruction Fields:

rrr - destination register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.34 MOV (Logical Move)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[s]$

Assembler:

Syntax: `mov r,s`

Example: `mov 4,0`

copies GReg[0] to GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Move the contents of the source General Register *s* to the destination General Register *r*.

Instruction Format

Instruction Set

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.35 NOTIFY (Notify to ARM platform)

Operation:

```
if (jjj & 4 == 0)
{
    if (jjj&2 == 2)
        HE[CCR] ← 0
    if (jjj&1== 1)
        HI[CCR] ← 1
}
else if (jjj == 4)
    EP[CCR] ← 0
else
```

(CCR stands for Current Channel Register)

Assembler:

Syntax: notify jjj

Example: notify 3

clears the HE bit for the current channel and sends an interrupt to the Host for the current channel

CPU Flags: Unaffected

Cycles: 1

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required, sends an interrupt to the corresponding ARM platform by setting the appropriate flag if required (HI for the corresponding channel number).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	1

jjj - Channel Flags field:

000 - unused

001 - set HI for the current channel

010 - clear HE for the current channel

011 - clear HE, set HI for the current channel

100 - clear EP for the current channel

101 - RESERVED

110 - RESERVED

111 - RESERVED

47.5.2.36 OR (Logical OR)

Operation:

$GReg[r] \leftarrow GReg[s] \mid GReg[r]$

Assembler:

Syntax: `or r,s`

Example: `or 3,6`

ORs GReg[3] and GReg[6] and stores the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Instruction Set

Description: Performs the OR of the source General Register *s* and the destination General Register *r*, and stores the result in the destination General Register *r*.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.37 ORI (Logical OR with Immediate Value)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[r] \mid \text{immediate}$

Assembler:

Syntax: `ori r,immediate`

Example: `ori 1,56`

ORs GReg[1] and the decimal value 56 and stores the result in GReg[1]

CPU Flags: unaffected

Cycles: 1

Description: Performs an OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:**rrr - register field:**

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

47.5.2.38 RET (Return from Subroutine)**Operation:**

PC ← RPC

Assembler:

Syntax: ret

CPU Flags: Unaffected

Cycles: 2

Description: Return from subroutine.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

47.5.2.39 REVB (Reverse Byte Order)

Operation:

$GReg[r] : \{B3, B2, B1, B0\} \leftarrow GReg[r] : \{B0, B1, B2, B3\}$

Assembler:

Syntax: revb r

Example: revb 5

reverses bytes order in GReg[5]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse the byte order of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	0

Instruction Fields:

rrr - register field:

- 000 - GReg[0]
- 001 - GReg[1]
- 010 - GReg[2]
- 011 - GReg[3]
- 100 - GReg[4]
- 101 - GReg[5]
- 110 - GReg[6]
- 111 - GReg[7]

47.5.2.40 Reverse Low Order Bytes(REVBLO)

Operation:

$GReg[r] : \{B3, B2, B0, B1\} \leftarrow GReg[r] : \{B3, B2, B1, B0\}$

Assembler:

Syntax: revblo r

Example: revblo 0

reverses low order bytes in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse both low order bytes of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	1

Instruction Fields:**rrr - register field:**

000 - GReg[0]

001 - GReg[1]

47.5.2.41 ROR1 (Rotate Right by 1 Bit)**Operation:**

$$\text{GReg}[r] : \{b_0, b_{31}, b_{30}, \dots, b_1\} \leftarrow \text{GReg}[r] : \{b_{31}, b_{30}, \dots, b_1, b_0\}$$
Assembler:

Syntax: ror1 r

Example: ror1 3

rotates bits to the right in GReg[3]

CPU Flags: Unaffected

Instruction Set

Cycles: 1

Description: Rotate the bits of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	0

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.42 RORB (Rotate Right by 1 Byte)

Operation:

$\text{GReg}[r] : \{B0, B3, B2, B1\} \leftarrow \text{GReg}[r] : \{B3, B2, B1, B0\}$

Assembler:

Syntax: `rorb r`

Example: `rorb 2`

rotates bytes to the right in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Rotate the bytes of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	1	0

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.43 SOFTBKPT (Software Breakpoint)**Operation:**

Stops the current script and enters debug mode

Assembler:`softbkpt`

CPU Flags: Unaffected

Description: When the core executes this instruction, it has the same effect as receiving a debug request from the OnCE or via the external debug request input: the script execution halts, the PCU enters its debug state and waits for the OnCE commands that are described in [OnCE and Real-Time Debug](#).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

47.5.2.44 ST (Store Register)**Operation:** $[GReg[b] + displacement] \leftarrow GReg[r]$ `if (transfer_error)`

Instruction Set

DF ← 1

else

DF ← 0

Assembler:

Syntax: st r, (b, displacement)

Example: st 7, (0,9)

stores the value from GReg[7] into memory at address obtained by adding decimal value 9 to GReg[0]

CPU Flags: DF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to store on the DM bus. The data sent on the bus comes from the source General Register r. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	r	r	r	d	d	d	d	d	b	b	b

Instruction Fields:

rrr / bbb - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

dddd - displacement value:

00000 - 0

00001 - 1

...

11111 - 31

47.5.2.45 STF (Store Register in Functional Unit)

Operation:

```
[fu_address] ← GReg[r] 0
```

```
if (transfer_error) 0
```

```
DF ← 1 0
```

```
else 0
```

```
DF ← 0
```

fu_address is an 8-bit field

Assembler:

Syntax: `stf r, fu_address`

Example: `stf 3, 0x2B`

stores the 32-bit contents of GReg[3] to the Burst DMA register MD; waits until the flush to external memory is completed

CPU Flags: DF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and sends the contents of the source General Register r on the bus. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Table 47-47. Instruction Format

47.5.2.46 SUB (Subtract)

Operation:

$GReg[r] \leftarrow GReg[r] - GReg[s]$

$T \leftarrow (GReg[r] == 0)$

Assembler:

Syntax: `sub r,s`

Example: `sub 4,7`

SUBtracts GReg[7] from GReg[4] and stores the result in GReg[4]

CPU Flags: T

Cycles: 1

Description: Subtracts the source General Register *s* from the destination General Register *r*, and stores the result in the destination General Register *r*. The T flag is set if the result of the operation is 0; it is cleared if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	0	s	s	s

Instruction Fields:

47.5.2.47 SUBI (Subtract with Immediate)**Operation:** $GReg[r] \leftarrow GReg[r] - \text{immediate}$ $T \leftarrow (GReg[r] == 0)$ **Assembler:**

Syntax: sub r,immediate

Example: sub 1,255

SUBtracts decimal value 255 from GReg[1] and stores the result in GReg[1]

CPU Flags: T

Cycles: 1

Description: Subtracts a 0-extended 8-bit immediate value from a General Register; stores the result in the General Register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

47.5.2.48 TST (Test with Zero)

Operation:

$T \leftarrow ((\text{GReg}[s] \ \& \ \text{GReg}[r]) \neq 0)$

Assembler:

Syntax: `tst r,s`

Example: `tst 2,3`

ANDs GReg[2] and GReg[3] and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of the source General Register s and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	0	s	s	s

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

47.5.2.49 TSTI (Test Immediate)**Operation:**

$$T \leftarrow ((\text{GReg}[r] \ \& \ \text{immediate}) \neq 0)$$
Assembler:Syntax: `tsti r,immediate`Example: `tsti 5,13`

ANDs GReg[5] and decimal value 13 and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of a 0-extended 8-bit immediate value and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Set

001 - GReg [1]
010 - GReg [2]
011 - GReg [3]
100 - GReg [4]
101 - GReg [5]
110 - GReg [6]
111 - GReg [7]

iiiiiii - immediate value:

00000000 - 0
00000001 - 1
...
11111110 - 254
11111111 - 255

47.5.2.50 XOR (Logical Exclusive OR)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[s] \wedge \text{GReg}[r]$

Assembler:

Syntax: `xor r,s`

Example: `xor 0,3`

XORs GReg[0] and GReg[3] and stores the result in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the eXclusive OR of the source General Register s and the destination General Register r, and stores the result in the destination General Register r.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	0	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg [0]
 001 - GReg [1]
 010 - GReg [2]
 011 - GReg [3]
 100 - GReg [4]
 101 - GReg [5]
 110 - GReg [6]
 111 - GReg [7]

47.5.2.51 XORI (Exclusive OR with Immediate)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[r] \wedge \text{immediate}$

Assembler:

Syntax: `xori r,immediate`

Example: `xor 7,5`

XORs GReg[5] and decimal value 5 and stores the result in GReg[7]

CPU Flags: Unaffected

Cycles: 1

Description: Performs an eXclusive OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg [0]
 001 - GReg [1]
 010 - GReg [2]
 011 - GReg [3]

Software Restrictions

100 - GReg [4]

101 - GReg [5]

110 - GReg [6]

111 - GReg [7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

47.5.2.52 YIELD, YIELDGE (DONE, Yield)

By default, unsupported assembler syntax. Can be aliased to the corresponding done instructions (yield = done 0; yieldge = done 1). Refer to the done instruction description [DONE \(DONE, Yield\)](#).

47.6 Software Restrictions

47.6.1 Unsupported Burst DMA Access Sequence

The SDMA does not support triggering a pre-fetch followed by a flush of the Burst DMA without reading or writing any data. If the flush occurs while the background pre-fetch DMA operation is still in progress, it could result in un-defined behavior.

An example of the sequence which could result in undefined results is shown in the following example:

Instruction sequence not supported

```
stf r1, MSA|PF          ; Update source address, triggers data pre-fetch in the
                        ; background
mov R0,R0               ; Execute multiple assembly instructions, none of which
                        ; read
mov R0,R0               ; or write data to/from MD
stf MD|SZ0|FL          ; Flush FIFO without writing data. If the pre-fetch is still
                        ; in progress when this instruction is executed, there
                        ; could be undefined operation
```

A work-around to avoid any undesirable results is to first read MD to ensure the pre-fetch is complete before the flush is attempted.

Work-Around to previous example

```

stf r1, MSA|PF      ; Update source address, triggers data pre-fetch.
mov R0,R0           ; Execute multiple assembly instructions, none of which
                   ; read
mov R0,R0           ; or write data to/from MD
ldf r2, MD          ; dummy read of MD to ensure pre-fetch is complete
                   ; before the next instruction
stf MD|SZ0|FL      ; Flush FIFO without writing data

```

47.7 Application Notes

47.7.1 Data Structures for Boot Code and Channel Scripts

SDMA boot code downloads the different channel contexts and the scripts that will be executed on SDMA channels during the application.

The boot code is run after reset when channel 0 is started by the ARM platform. The boot code is also known as channel 0 script.

The boot code is based on the Channel Control Block (CCB) and Buffer Descriptor (BD) mechanisms that are data structures located into the ARM platform memory space. With these data structures, it is possible to instruct SDMA to download scripts and contexts but also to dump a context or a script to a destination data buffer. Channel scripts also use the CCB and BD data structures to pass instructions and/or pointers to data to be copied.

The format, processing, and field definition of the CCB and BD are defined and performed entirely by the software script rather than the SDMA hardware. An overview of the format and structure is provided here, but for complete details refer to the SDMA software documentation (see [SDMA Scripts](#)).

The CCB and BD data structures are accessed by SDMA using DMA and processed by the SDMA scripts. The ROM contains common sub-routines for processing these data structures which may be called by the bootload and channel scripts.

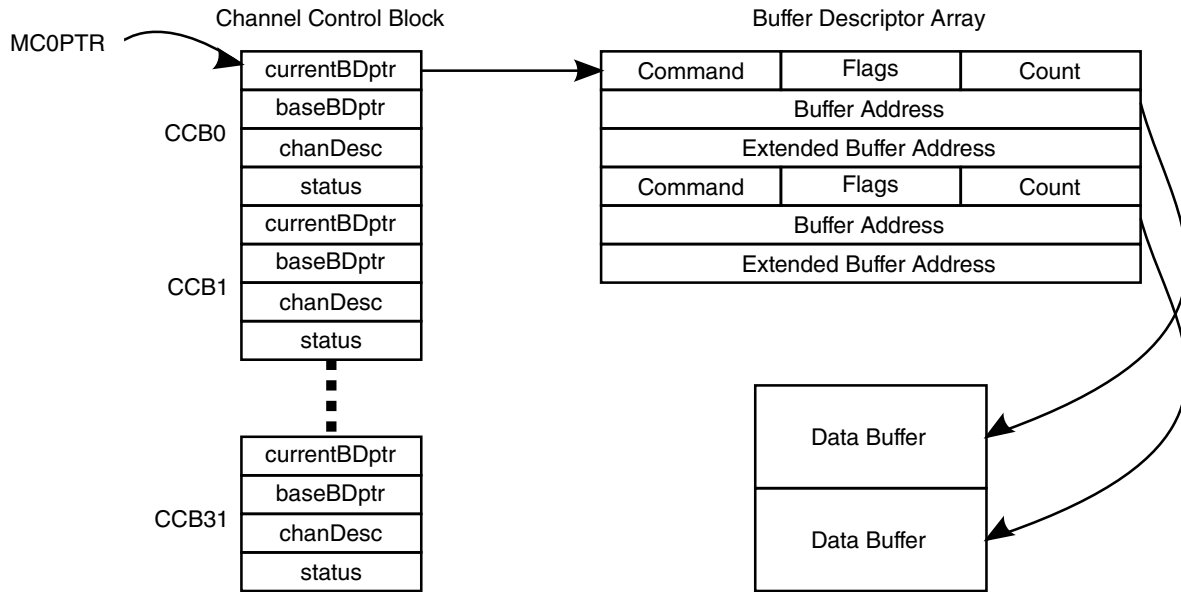

Figure 47-16. Data Structures Layout

The previous figure shows an example how these data structures are linked to pass command and pointers to data buffers. The SDMA's MCOPTR register holds the base address of the Channel 0 Control Block (CCB0). The Channel 0 control block holds a pointer to the array of buffer descriptors. The buffer descriptors are used to tell the channel 0 (boot channel) what to do as described [Buffer Descriptor Format](#).

47.7.1.1 Buffer Descriptor Format

Buffer descriptors are three longs (32-bit words) in size as, shown in the figure found here.

A buffer descriptor describes the properties of the data buffer it points to. The buffer descriptors can be used for linear or circular data buffers in the ARM platform processor memory. The CCB contains a pointer to the base BD as well as the current BD.

Table 47-48. Buffer Descriptor

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Command								-	-	L	R	I	C	W	D	Count															
Buffer Address																															
Extended Buffer Address																															

Table 47-49. Buffer Descriptor Field Descriptions

Field	Description
31-24 Command	Command. The command field is used to differentiate operations performed within a script when the script accesses this particular buffer descriptor. The use of this field can be defined by the script. The command values defined for the bootload script are defined in Buffer Descriptor Commands for Bootload scripts . Refer to the individual script definition in script library documents in SDMA Scripts for command field definitions for other scripts.
23	Reserved
22	Reserved
21 L	Last Buffer Descriptor: This bit is set in SDMA IPC scripts to indicate to the receiving Core that the transfer has ended. Whenever the source finishes transferring the count it wanted to transfer, it sets LAST_BIT in the destination BD, to let the destination know that transfer is over. This bit also tells the destination software that when it processes the destination BDs, they need not process any BD after the BD with the LAST_BIT set. For example, when the DSP prepares a single buffer descriptor with count equals to 25 and ARM platform prepares a single buffer descriptor with count equals 100. When 25 bytes have been transferred from DSP to ARM platform, the DSP buffer descriptor is normally closed while the ARM platform buffer descriptor will have the L bit set and the byte count updated to 25.
20 R	erroR. Indicates an error occurred on the channel's buffer descriptor requested command. Some scripts may overwrite the command field with an error code indicating the source of the error. 0 No Error 1 Error
19 I	Interrupt. When SDMA has finished to process data transfer attached to this buffer descriptor, send an interrupt to the ARM platform. 0 No Interrupt 1 Interrupt the processor when BD is complete
18 C	Continuous. This buffer is allowed to receive multiple transmit buffers or is allowed to transmit to multiple receive buffers. The Continuous bit is decoded at the end of the processing of a BD to determine if the SDMA script must open a new BD to potentially continue the data transfer. 0 No further buffer descriptors 1 SDMA should move to the next Buffer descriptor after this one
17 W	Wrap. Indicates if this buffer descriptor is the last one for the channel control block. When encountering this bit set, the SDMA scripts updates the CurrentBD pointer to point to the first Buffer Descriptor of the array. This bit is set if the ARM platform wants to organize the array of BD in a circular way (like a ring). When all BD have been processed and if Wrap bit and CONTinuous bit are set in the last BD, the SDMA script will wrap around and it will try to re-open the first BD. 0 No Error 1 Wrap to first buffer descriptor after this one is processed.
16 D	D - "Done": bit 16: indicates the "ownership" of the buffer descriptor. When D=0 the host owns the buffer descriptor; when D=1 SDMA owns the buffer descriptor. In the case of the channel 0, D=1 indicates the SDMA has not yet processed this buffer, D=0 indicates the SDMA has processed this buffer. 0 ARM platform owns the buffer. 1 SDMA owns the buffer
15-0 Count	Count. the count field (bit 15-0) indicates the size of the data to be transmitted, the size of the data buffer pointed to by the buffer descriptor. The SDMA memory structure is different for program memory (16-bits shorts/half-words) and data memory (32-bits long). For channel 0 buffer descriptors, Count is expressed in 16-bit half-words when PM is addressed and in 32-bit words when DM is addressed. Count is typically expressed in bytes for other channel scripts, but the unit is dependant on the script.
31-0	Buffer address. Address pointer to the data buffer.
31-0	Extended buffer address. Additional pointer or other information required by some scripts.

The buffer descriptors form an array of programmable size. If the last buffer descriptor is marked by the Wrap flag-bit W=1, the array of buffer descriptor is treated as a ring with some logically continuous portion owned by the ARM platform with D=0, and the remainder owned by the SDMA with D=1. The count field of the buffer descriptor indicates how much data has been transmitted.

If ARM platform has prepared 3 buffers to be filled by the SDMA script, it has also prepared 3 BD, one for each buffer. The *Cont* and *Wrap* bits are used to organize the buffers in a circular way. For example, *CONTInous* bit is set to 1 in the 2 first BDs and *Wrap* is set in the 3rd BD. The SDMA script opens and processes BD#1. Since *CONTInous* bit is set for this BD, the SDMA will open the second BD and it will process it. Each time a BD is processed, its *Done* bit is reset by the SDMA. After the 3rd BD, if *CONTInous* is not set but if *Wrap* is set, the SDMA script stops here and the next time the channel will be triggered, the script will open the BD pointed by the currentBDptr pointer of the CCB and it will correspond to the first buffer descriptor.

If the *CONTInous* bit and *Wrap* bits are both set in the 3rd BD, the script will close it and it will try to open the first BD. An error may occur at this point if the BD#1 has already been processed and its *Done* bit is 0. The SDMA script cannot process a BD with a *Done* bit to 0. It means the BD is not ready to be processed. To avoid this situation, the *CONTInous* bit should not be set for the last BD if *Wrap* is set, and the Interrupt flag must set for the last BD. It will warn the owner of the BD that all the BDs have been processed and it has to re-set to 1 the *Done* bit of all the BD's if it desires the SDMA to fill them again. Basically, if the ARM platform expects the SDMA to fill up the buffers in a circular fashion, then it's the responsibility of the ARM platform to set the *Done* bit of a buffer descriptor at an appropriate time.

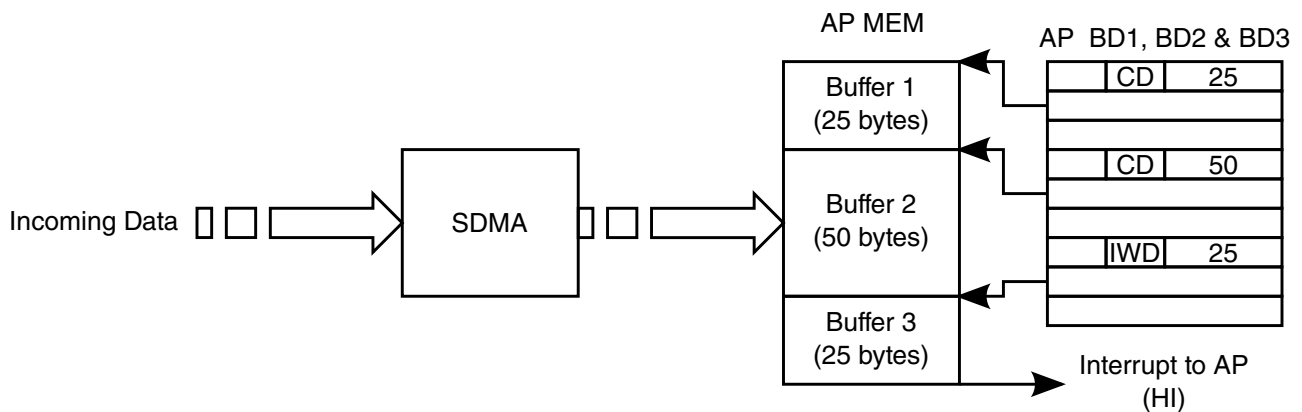

Figure 47-17. Buffer Descriptor Flow

The previous figure shows an example buffer descriptor flow. When the incoming data is stored and fills the first buffer of 25 bytes, the SDMA script opens the second BD because the CONTinuous bit was set. Then next incoming data is put in the second buffer. After receiving 50 bytes, the second buffer descriptor is also closed. The Done bit is reset and the third BD is opened. After receiving another 25 bytes, the third buffer is full and an interrupt is sent to the ARM platform because the Interrupt flag is set in the 3rd BD. The CONTinuous flag is not present the transfer is over. The next time the script will be triggered, the BD to be opened will be the first buffer descriptor since the Wrap flag was set in the 3rd BD. It is the ARM platform responsibility to set the Done bit of all the BD if it wants to use the same buffers.

47.7.1.2 Buffer Descriptor Commands for Bootload scripts

The command field of the buffer descriptor is defined separately for each script.

The following table lists the buffer descriptor commands defined for the channel 0 bootload script.

Table 47-50. Channel Zero Buffer Descriptor Commands

Command Field (binary)	Command	Description	Buffer Address	Extended Buffer Address
0000_0001 (0x01)	C0_SET_DM	Load SDMA data memory (RAM) from ARM platform memory buffer	ARM platform memory source address	SDMA memory destination address
0000_0010 (0x02)	C0_GET_DM	Copy SDMA data memory (RAM) to ARM platform memory buffer	ARM platform memory destination address	SDMA memory source address
0000_0100 (0x04)	C0_SET_PM	Load SDMA program memory (RAM) from ARM platform memory buffer	ARM platform memory source address	SDMA memory destination address
0000_0110 (0x06)	C0_GET_PM	Copy SDMA program memory (RAM) to ARM platform memory buffer	ARM platform memory destination address	SDMA memory source address
cccc_c111 (0x07 CHN)	C0_SETCTX	Load Context for channel cccc into SDMA RAM from ARM platform memory buffer	ARM Platform memory source address	-
cccc_c011 (0x03 CHN)	C0_GETCTXT	Copy Context for channel ccccc from SDMA RAM to ARM platform memory buffer	ARM platform memory destination address	-

The Channel 0 bootload commands are summarized as follows:

- **C0_SET_[PM-DM]**: load the buffer descriptor data in the SDMA local memory at the address pointed to by the "extended buffer address" field. The SDMA RAM can be seen as a Program Memory (PM, 16-bit address) or Data Memory (DM 32-bit address). When C0_SET_PM is used, the count field is expressed in "shorts" (16-bit

half words), this command can be used to download scripts. When C0_SET_DM is used, the count field is expressed in "long" (32-bit words), this command can be used to download channel contexts to the context channel area in RAM.

- C0_GET_[PM-DM]: write to the buffer descriptor's data buffer the content of the SDMA local memory from the address pointed to by the "extended buffer address" field for the length defined by the count in the buffer descriptor. C0_GET_PM is used to dump some part of the Program Memory (may be used to dump context of a channel), therefore count is expressed in "shorts"; while C0_GET_DM is used to dump to the buffer descriptor's data buffer, so the count field is in "longs."
- C0_SETCTX: load a context into the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using the channel number the script computes the offset of the context data pointer for the channel relative to the context page base to use as the destination address in SDMA memory. Then the C0_SET_DM command explained above is invoked to load SDMA RAM from memory. The counter indicates the size in words of the context structure.
- Command value: (in binary) cccc c111, where cccc is the channel number (5 bits). For instance, 0x0F means set context for channel 1, 0xFF means set context for channel 31.
- C0_GETCTX: write to the buffer descriptor's data buffer the content of the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using this channel number, the script computes the offset of the context data pointer for the channel relative to the context page base to use as the source address for the copy. Then the C0_GET_DM command explained above is invoked to copy the context to memory. The counter indicates the size in words of the context structure.
- Command value: (in binary): cccc c011, where cccc is the channel number (5 bits). For instance, 0x03 means get context of channel 1, 0xFB means get context of channel 31.

NOTE

To download channel context, C0_SETDM and C0_SETCTXT command can be used but the second one is easier because the channel number is embedded into the command field, whereas with the C0_SETDM, the pointer to the channel context area must be written into the extended buffer address field of the buffer descriptor.

47.7.1.3 Example of Buffer Descriptors for Channel 0.

Figure 47-19 illustrates the buffer descriptors that must be set in ARM platform memory space, before execution of boot code, to download contexts and scripts of channels 1, 4, and 10. After boot code execution, SDMA memory will be populated with the different contexts and scripts as presented in the following figure.

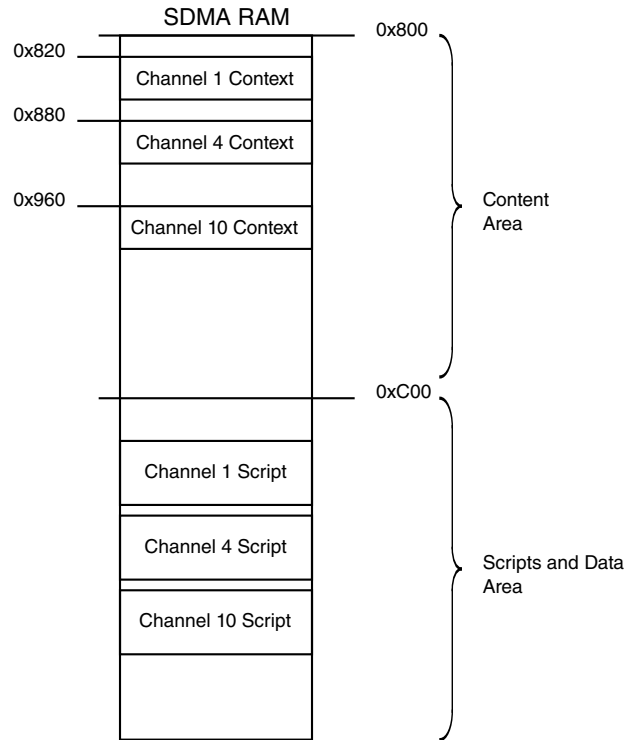

Figure 47-18. Example of SDMA RAM After Boot Session

47.7.1.4 Channel Context

There are 32 channel context memory structures pointed to by the local save area pointer. These channel context memory structures are fixed.

The script in the SDMA computes the memory offset for a given channel based on the structure length and channel number. Figure below shows the structure of the channel context as it is saved in the SDMA local memory (RAM).

A channel context consists in 24 words, one per register. A total of 32 words are reserved for every channel. The additional 8 words are called scratch ram and they are dedicated to each channel. This memory area is commonly used for stack management.

The structure is divided in 4 areas:

- Channel status registers
- General purpose registers
- Functional units state registers reflecting the state of the ARM platform DMAs (Burst and Peripheral DMA).
- Scratch RAM

The details of the channel context status registers are described in the following figure.

The PC field of the first long register must point to the SDMA RAM address where the script that will be executed on the channel is located and this value equals the one stored in the extended buffer address of the buffer descriptor with C0_SETPM command.

31	30	29	16	15	14	13	0
SF	—	RPC	T	—	PC		
LM		EPC	DF	—	SPC		

SF: Source fault while loading data
 RPC: Return program counter
 T: Test bit: status of arithmetic and test instructions
 PC: Program counter
 LM: Loop mode
 EPC: Loop end program counter
 DF: Destination fault while storing data
 SPC: Loop Start program counter

Figure 47-20. SDMA State Registers (ShPC, ShLoop)

47.7.2 Typical Data Transfer Supported by SDMA DMA Units

This section presents a library of SDMA scripts that perform data transfers through the peripheral DMA and the burst DMA units.

The ARM platform memory and peripherals are devices that either the peripheral DMA or the burst DMA can access. The scripts are given for a peripheral DMA whose address registers are programmed in incremented mode when internal memory is involved. See the following table for the summary.

Table 47-51. Typical Data Transfers Summary

Data Transfer	Peripheral DMA	Burst DMA	Comments
ARM platform External Memory ↔ ARM platform External Memory		3	Copy mode Script example, see Burst DMA Unit Copy Mode and External Memory to External Memory .
ARM platform Peripheral ↔ ARM platform Peripheral	3		Copy mode if same data path width Script example, see Peripheral to Peripheral Transfer .
ARM platform External Memory ↔ ARM platform Peripheral	3	3	Data transit through SDMA Script example, see Transfer Between Peripheral and External Memory .
ARM platform External Memory ↔ ARM platform Internal Memory		3	Copy mode Script example, see Transfer Between External Memory and Internal Memory .
ARM platform Internal Memory ↔ ARM platform Internal Memory		3	Copy mode Script example, see Internal Memory to Internal Memory .
ARM platform Internal memory ↔ ARM platform Peripheral	3		Data transit through SDMA Script example, see Transfer Between Peripheral and Internal Memory .

NOTE

These scripts are provided as examples of how to use DMA blocks to perform required data transfers: They are not "official" programs.

47.7.2.1 External Memory to External Memory

This section describes the SDMA script that performs data moves in external memory.

For this particular data transfer, only the burst DMA is used. It is programmed in copy mode, so no data transmits through an SDMA general register.

The SDMA core only monitors data transfer status. It is assumed source and destination address values are already present in two SDMA general registers (r1 and r2). For this example, it is also assumed that a 32-bit word-to-move for source-to-destination address is present in r0 and equals 64.

Data Moves in External Memory

```

1      stf r1,MSA           // Source address setup
2      stf r2,MDA           // Destination address setup
3      ldi r0,0x64          // 64 words must be transferred from MSA to
MDA
4      ldi r1,0x8

MAIN_XFER:
5      cmphs r0,r1          // Is r0 >= 0x8
6      bf LAST_XFER        // If not, jump to last transfer label
7      stf r1,MD|CPY        // Copy 8 words from MSA to MDA address.
8      subi r0,0x8          // Decrement counter
9      jmp MAIN_XFER        // return to main transfer loop

LAST_XFER:
10     stf r0,MD|CPY        // perform last transfer

```

All instructions are performed in one cycle (jumps excepted). Instruction 7 triggers a copy transfer: A read burst access of 8-word starts, data is staged in MD and then a write burst of 8 words is executed. Instruction 8, 9, 5, and 6 are executed while the burst access is in progress. If this access is not complete when instruction 7 is executed a second time, SDMA stalls on this instruction as long as the previous copy transfer is not over. In this case, the instruction is no longer a one-cycle instruction.

During the main loop (MAIN_XFER), r1 always equals 8, so burst lengths are 8 words. On the last ldf |CPY instruction (10), r1 equals the remainder of r0 divided by 8; therefore, the length of bursts triggered in copy mode equal r1 value, which is between 1 and 7.

47.7.2.2 Peripheral to Peripheral Transfer

For this data transfer, only the peripheral DMA is used.

It is programmed in copy mode, so no data will transmit through the SDMA general register used in the ldf instruction, but the contents of the general register are lost. The SDMA core only monitors the transfer.

47.7.2.2.1 Source and Destination Target Have the Same Data Path Width

When the source and destination target have the same data path width, the following is true:

- Source target is a *half-word* (16-bit) peripheral located at address 0x1002.
- Destination is a *half-word* (16-bit) peripheral located at address 0x2006.

It is assumed the address values are already present in two SDMA general registers (r1, r2). The script for a transfer of 10 half-word is as follows:

Same Data Path Width for Source and Destination

```
//SETUP SECTION
1      stf r1, PSA|SZ16|F           //r1=0x1002 Source address register setup
2      stf r2, PDA|SZ16|F           //r2=0x2006 Destination address register
setup
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0xa                   //loop counter is 10
//MAIN LOOP TRANSFER
copy_loop:
5      loop 2,0
6      ldf r7,PD|CPY                //Reads 1 half-word from src and writes to
dest.
7      yield
8      bdf ERROR_DURING_XFER
ERROR_ADDR_SETUP:
           //correction of PSA/PDA setup and jumps to main loop transfer
ERROR_DURING_XFER:
           //flag error is set,
           //PS can be read to know if error occurs during read or write access.
```

If a data transfer must occur between two word peripherals, only the setup section should be updated. The transfer itself is always performed by the hardware loop instruction.

All instructions are executed in one cycle (change of flow excepted). On instruction 6, a single read access is triggered, read data is staged in PD, and a write-to-destination is executed. When the transfers are in progress, the SDMA can execute the next instructions in parallel. If instruction 6, which performs the copy transfer, is executed while the previous access is not over, SDMA is stalled and instruction ldf is a multi-cycle instruction.

47.7.2.2.2 Source and Destination Target Have a Different Data Path Width

When the source and destination target have a different data path width, copy mode cannot be used, and any attempt to initiate a copy transfer immediately raises an error, which is stored in the SF flag.

The following example shows the SDMA code that could transfer 10 words from a *word* (32-bit) peripheral to a *half-word* peripheral whose addresses are preliminary and stored in r1 and r2.

Different Data Path Width for Source and Destination

```
//SETUP SECTION
1      stf r1, PSA|SZ32|F|PF          //r1=0x1000 and prefetch data
2      stf r2, PDA|SZ16|F           //r2=0x2006
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0xa                   //loop counter is 10
//MAIN LOOP TRANSFER
main_loop_xfer_16_16:
5      loop 6,0
6      ldf r7,PD                    //copy 32-bit of PD in r7
7      stf r7,PD                    //store 16 LSB of r7 in PD and a flush is
executed
8      rorb r7
9      rorb r7                       //16 MSB --> 16 LSB
10     stf r7,PD                    //store 16 LSB of r6 in PD and a flush.
11     yield
```

On instruction 1, when the source address register is programmed and a data prefetch is required, a read access is executed. In parallel, the SDMA executes instructions 2 to 5. On instruction 6, the SDMA tries to read data that was fetched by instruction 1. If data is ready, the ldf will be a one cycle instruction; otherwise, the SDMA is stalled as long as the read access is not finished. Then, the 16 LSB of the read data is stored in PD and automatically flushed to the destination peripheral. In parallel, the SDMA executes the rotation instructions (8, 9), and stores the 16 MSB of the read data into PD. If a previous write access is finished, instruction 10 will be a one-cycle instruction.

The main loop transfer may appear inefficient, but due to wait states imposed to the peripheral DMA each time an external access is performed, a software pipeline is in place. During the time needed to flush PD, the SDMA executes the move and rotation operations. SDMA executes instructions in parallel with DMA accesses.

47.7.2.3 Transfer Between Peripheral and External Memory

47.7.2.3.1 Peripheral to External Memory Transfer

A transfer from a peripheral to the external memory controller involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from word peripheral to the external memory would be as follows:

Peripheral to External Memory Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1      stf r1, PSA|SZ16|F|PF          //r1=0x1000 and prefetch 32-bit data
2      stf r2, MDA                    //r2=0x2000, setup burst DMA destination
address
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0x64                   //loop counter is 100
5
//MAIN LOOP TRANSFER
6      loop 3,0
```

Application Notes

```

7          ldf r1,PD|PF          // read 32 bits of PD and initiate a new read
access.
8          stf r1,MD|32          // store 32 bits of r1 in the MD fifo.
9          yield
10         ldf r1,PD             // last word data is read
11         stf r1,MD|32|FL       // to flush all remaining bytes of MD

```

On instruction 1, the source address register of the peripheral DMA is programmed and data is fetched. This data is stored in PD and the SDMA reads PD during instruction 7, which is a one-cycle instruction that is read-access finished. On the same instruction (7), a data prefetch is required and a read access to the source peripheral is executed. In parallel, the SDMA stored the previous read data into the data register of MD. When MD (which is an eight-word FIFO) is full, a burst write access is executed to empty the FIFO. As long as the next SDMA instructions do not access the burst DMA, they will be one-cycle instructions. The following figures show how the peripheral DMA and burst DMA work in parallel.

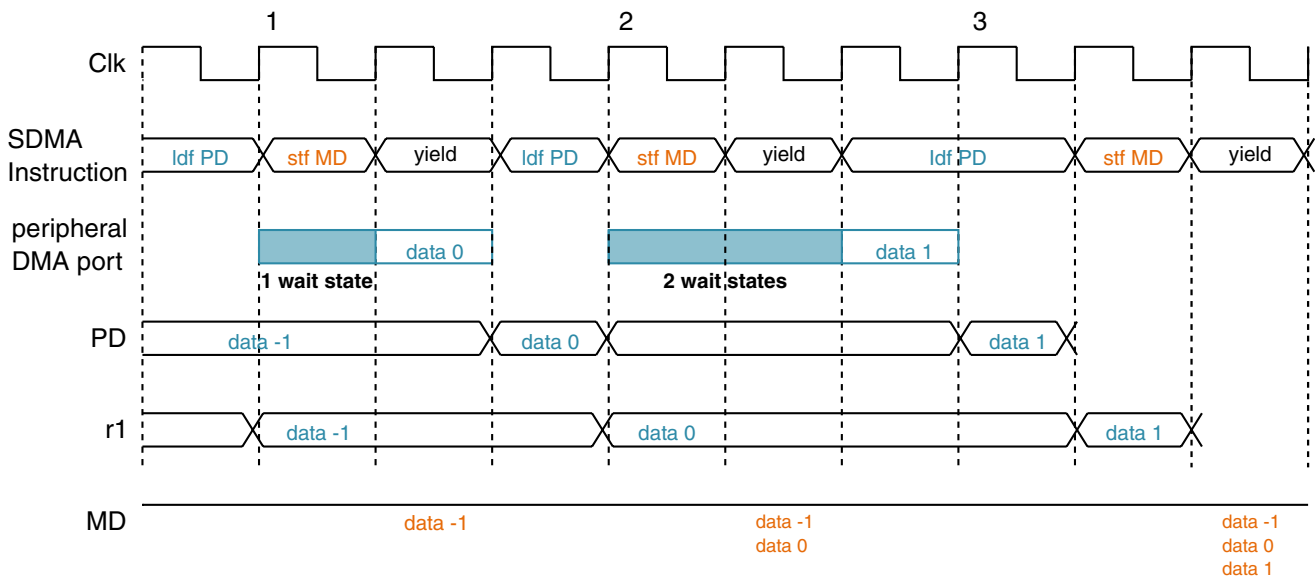

Figure 47-21. Peripheral to External Memory Example (1)

As seen in the figure above, the read access triggered by the ldf PD instruction is symbolized by the blue bar when in progress. After wait states, the read data (data 0, data 1) is stored in PD on the clk rising edge. On edge 2, data 0 is available in PD so it can be transferred to the SDMA general register r1, and then stored in MD FIFO. On edge 3, data 1 is not in PD; therefore, SDMA is stalled on the ldf instruction, which lasts two cycles. The figure below shows an example of when MD FIFO is full with data.

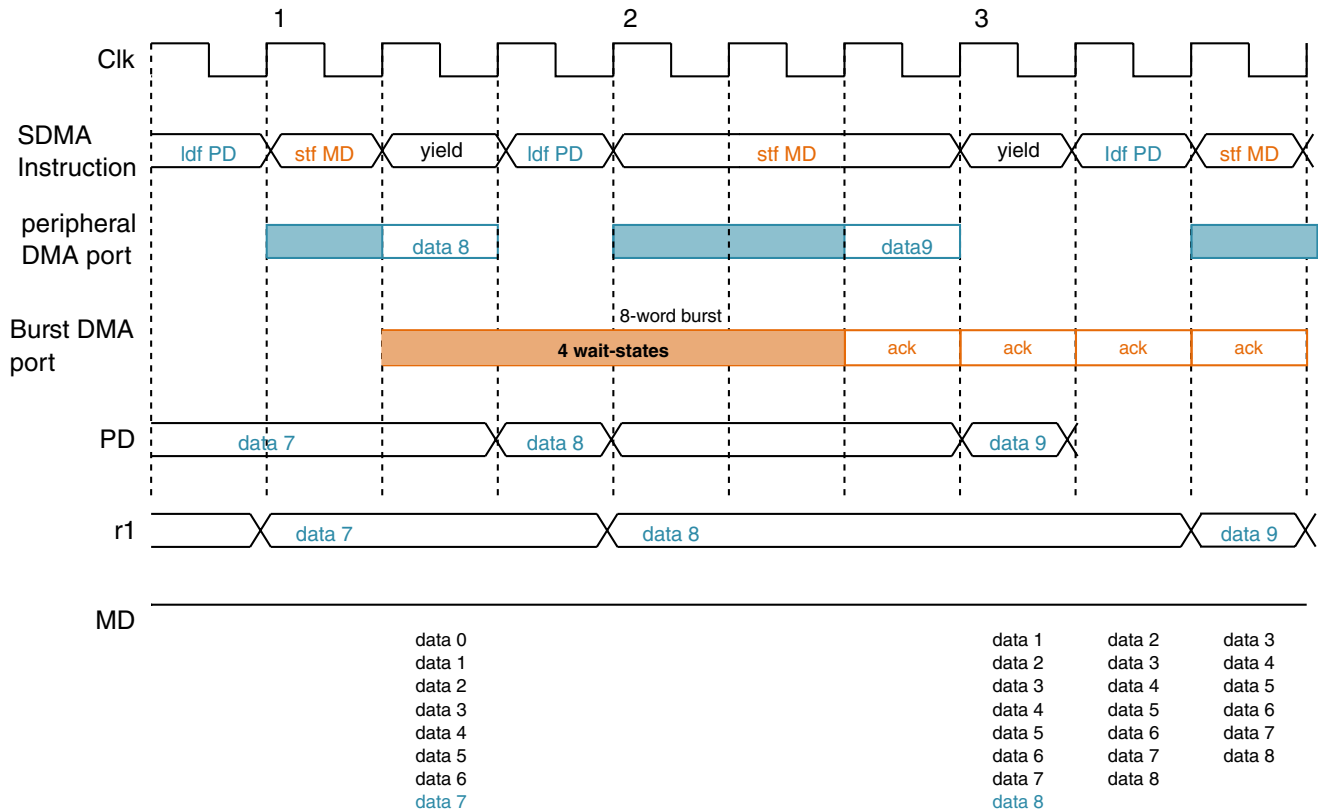

Figure 47-22. Peripheral to External Memory Example (2)

In the previous figure, the write bar means the burst DMA is performing a write burst access. The latency to have the first write acknowledge is four cycles. SDMA is stalled on instruction stf because no acknowledge was received, MD FIFO is full, and there is no empty slot to store data 9. When an acknowledge is sampled by the burst DMA, FIFO is shifted and data 8 is written. As long as there is at least one empty slot in MD FIFO, the stf MD instruction lasts one cycle.

47.7.2.3.2 External Memory to Peripheral Transfer

A transfer from the external memory to a peripheral involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from external memory to a word peripheral would be as follows:

External Memory to Peripheral Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1      stf r1, MSA|PF           //r1=0x1000 and starts a 8-word read burst
2      stf r2, PDA|SZ32|P      //r2=0x2010, setup peripheral DMA destination address
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0x64             //loop counter is 100
//MAIN LOOP TRANSFER
6      loop 3,0
```

ARM Platform Memory Map and Control Register Definitions

```
7         ldf r1,MD|32|PF          // read 32 bits of MD and initiate a new read access
                                     // if MD is empty after this reading.
8         stf r1,PD                // store 32 bits of r1 in the PD.
9         yield
10        ldf r1,MD|32            // last word data is read
11        stf r1,PD                // last write access
```

On instruction 1, a read burst of 8 words begins. Read data is staged into MD. On instruction 7 (and if data is available in MD), 32 bits are copied into r1. Then instruction 8 writes them into PD and an automatic flush is executed. The SDMA core, peripheral DMA, and burst DMA can work in parallel as long as no SDMA instruction tries to start a new write access on the peripheral DMA while the previous access is still in progress, or as long as there is data in MD when the SDMA tries to read it.

47.7.2.4 Transfer Between External Memory and Internal Memory

Since the internal memory (ARM platform RAM) is accessed via the peripheral DMA and the external memory is accessed via the burst DMA, the SDMA scripts that are described in [Transfer Between Peripheral and External Memory](#) can be reused. The exception is that the peripheral DMA address registers (PSA or PDA, depending on the script) should be programmed in incremented mode rather than frozen mode.

47.7.2.4.1 Internal Memory to Internal Memory

The internal memory can only be accessed via the peripheral DMA, so the script described in [Peripheral to Peripheral Transfer](#) can be reused with a different programming of the peripheral DMA address registers.

47.7.2.4.2 Transfer Between Peripheral and Internal Memory

For this transfer, the peripheral DMA is also used in copy mode.

The SDMA script is very similar to the one described in [Peripheral to Peripheral Transfer](#), except for the peripheral DMA address registers programming.

47.8 ARM Platform Memory Map and Control Register Definitions

The ARM platform controls the SDMA by means of several interface registers. Those registers are described in the current section.

All registers are clocked with the SDMA clock (which means the ARM platform must ensure that the SDMA clock is running when it wants to access any register).

SDMAARM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

47.8.1 ARM platform Channel 0 Pointer (SDMAARM_MC0PTR)

Address: 20E_C000h base + 0h offset = 20E_C000h

SDMAARM_MC0PTR field descriptions

Field	Description
MC0PTR	Channel 0 Pointer contains the 32-bit address, in ARM platform memory, of channel 0 control block (the boot channel). Appendix A fully describes the SDMA Application Programming Interface (API). The ARM platform has a read/write access and the SDMA has a read-only access.

47.8.2 Channel Interrupts (SDMAARM_INTR)

Address: 20E_C000h base + 4h offset = 20E_C004h

SDMAARM_INTR field descriptions

Field	Description
HI[31:0]	The ARM platform Interrupts register contains the 32 HI[i] bits. If any bit is set, it will cause an interrupt to the ARM platform. This register is a "write-ones" register to the ARM platform. When the ARM platform sets a bit in this register the corresponding HI[i] bit is cleared. The interrupt service routine should clear individual channel bits when their interrupts are serviced, failure to do so will cause continuous interrupts. The SDMA is responsible for setting the HI[i] bit corresponding to the current channel when the corresponding <code>done</code> instruction is executed.

47.8.3 Channel Stop/Channel Status (SDMAARM_STOP_STAT)

Address: 20E_C000h base + 8h offset = 20E_C008h

SDMAARM_STOP_STAT field descriptions

Field	Description
HE	This 32-bit register gives access to the ARM platform Enable bits. There is one bit for every channel. This register is a "write-ones" register to the ARM platform. When the ARM platform writes 1 in bit <i>i</i> of this register, it clears the HE[<i>i</i>] and HSTART[<i>i</i>] bits. Reading this register yields the current state of the HE[<i>i</i>] bits.

47.8.4 Channel Start (SDMAARM_HSTART)

Address: 20E_C000h base + Ch offset = 20E_C00Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HSTART_HE																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_HSTART field descriptions

Field	Description
HSTART_HE	<p>The HSTART_HE registers are 32 bits wide with one bit for every channel. When a bit is written to 1, it enables the corresponding channel. Two physical registers are accessed with that address (HSTART and HE), which enables the ARM platform to trigger a channel a second time before the first trigger is processed.</p> <ul style="list-style-type: none"> This register is a "write-ones" register to the ARM platform. Neither HSTART[<i>i</i>] bit can be set while the corresponding HE[<i>i</i>] bit is cleared. When the ARM platform tries to set the HSTART[<i>i</i>] bit by writing a one (if the corresponding HE[<i>i</i>] bit is clear), the bit in the HSTART[<i>i</i>] register will remain cleared and the HE[<i>i</i>] bit will be set. If the corresponding HE[<i>i</i>] bit was already set, the HSTART[<i>i</i>] bit will be set. The next time the SDMA channel <i>i</i> attempts to clear the HE[<i>i</i>] bit by means of a <code>done</code> instruction, the bit in the HSTART[<i>i</i>] register will be cleared and the HE[<i>i</i>] bit will take the old value of the HSTART[<i>i</i>] bit. Reading this register yields the current state of the HSTART[<i>i</i>] bits. This mechanism enables the ARM platform to pipeline two HSTART commands per channel.

47.8.5 Channel Event Override (SDMAARM_EVTOVR)

Address: 20E_C000h base + 10h offset = 20E_C010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	EO																															
W	EO																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_EVTOVR field descriptions

Field	Description
EO	The Channel Event Override register contains the 32 EO[<i>i</i>] bits. A bit set in this register causes the SDMA to ignore DMA requests when scheduling the corresponding channel.

47.8.6 Channel BP Override (SDMAARM_DSPOVR)

Address: 20E_C000h base + 14h offset = 20E_C014h

SDMAARM_DSPOVR field descriptions

Field	Description
DO	This register is reserved. All DO bits should be set to the reset value of 1. A setting of 0 will prevent SDMA channels from starting according to the condition described in Runnable Channels Evaluation . 0 - Reserved 1 - Reset value.

47.8.7 Channel ARM platform Override (SDMAARM_HOSTOVR)

Address: 20E_C000h base + 18h offset = 20E_C018h

SDMAARM_HOSTOVR field descriptions

Field	Description
HO	The Channel ARM platform Override register contains the 32 HO[i] bits. A bit set in this register causes the SDMA to ignore the ARM platform enable bit (HE) when scheduling the corresponding channel.

47.8.8 Channel Event Pending (SDMAARM_EVTPEND)

Address: 20E_C000h base + 1Ch offset = 20E_C01Ch

SDMAARM_EVTPEND field descriptions

Field	Description
EP	<p>The Channel Event Pending register contains the 32 EP[i] bits. Reading this register enables the ARM platform to determine what channels are pending after the reception of a DMA request.</p> <ul style="list-style-type: none"> Setting a bit in this register causes the SDMA to reevaluate scheduling as if a DMA request mapped on this channel had occurred. This is useful for starting up channels, so that initialization is done before awaiting the first request. The scheduler can also set bits in the EVTPEND register according to the received DMA requests. The EP[i] bit may be cleared by the <code>done</code> instruction when running the channel <i>i</i> script. This a "write-ones" mechanism: Writing a '0' does not clear the corresponding bit.

47.8.9 Reset Register (SDMAARM_RESET)

Address: 20E_C000h base + 24h offset = 20E_C024h

SDMAARM_RESET field descriptions

Field	Description
31–2 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

SDMAARM_RESET field descriptions (continued)

Field	Description
1 RESCHED	When set, this bit forces the SDMA to reschedule as if a script had executed a <code>done</code> instruction. This enables the ARM platform to recover from a runaway script on a channel by clearing its HE[i] bit via the STOP register, and then forcing a reschedule via the RESCHED bit. The RESCHED bit is cleared when the context switch starts.
0 RESET	When set, this bit causes the SDMA to be held in a software reset. The internal reset signal is held low 16 cycles; the RESET bit is automatically cleared when the internal reset signal rises.

47.8.10 DMA Request Error Register (SDMAARM_EVTERR)

Address: 20E_C000h base + 28h offset = 20E_C028h

SDMAARM_EVTERR field descriptions

Field	Description
CHNERR	<p>This register is used by the SDMA to warn the ARM platform when an incoming DMA request was detected and it triggers a channel that is already pending or being serviced. This probably means there is an overflow of data for that channel.</p> <ul style="list-style-type: none"> An interrupt is sent to the ARM platform if the corresponding channel bit is set in the INTRMASK register. This is a "write-ones" register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the ARM platform or during SDMA reset. The CHNERR[i] bit is set when a DMA request that triggers channel <i>i</i> is received through the corresponding input pins and the EP[i] bit is already set; the EVTERR[i] bit is unaffected if the ARM platform tries to set the EP[i] bit, whereas, that EP[i] bit is already set.

47.8.11 Channel ARM platform Interrupt Mask (SDMAARM_INTRMASK)

Address: 20E_C000h base + 2Ch offset = 20E_C02Ch

SDMAARM_INTRMASK field descriptions

Field	Description
HIMASK	The Interrupt Mask Register contains 32 interrupt generation mask bits. If bit HIMASK[i] is set, the HI[i] bit is set and an interrupt is sent to the ARM platform when a DMA request error is detected on channel <i>i</i> (for example, EVTERR[i] is set).

47.8.12 Schedule Status (SDMAARM_PSW)

Address: 20E_C000h base + 30h offset = 20E_C030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARM_PSW field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–13 NCP[2:0]	The Next Channel Priority gives the next pending channel priority. When the priority is 0, it means there is no pending channel and the NCR value has no meaning. 0 No running channel 1 Active channel priority
12–8 NCR[4:0]	The Next Channel Register indicates the number of the next scheduled pending channel with the highest priority.
7–4 CCP[2:0]	The Current Channel Priority indicates the priority of the current active channel. When the priority is 0, no channel is running: The SDMA is idle and the CCR value has no meaning. In the case that the SDMA has finished running the channel and has entered sleep state, CCP will indicate the priority of previous running channel. 0 No running channel 1 Active channel priority
CCR[4:0]	The Current Channel Register indicates the number of the channel that is being executed by the SDMA. SDMA. In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel.

47.8.13 DMA Request Error Register (SDMAARM_EVTERRDBG)

Address: 20E_C000h base + 34h offset = 20E_C034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARM_EVERRDBG field descriptions

Field	Description
CHNERR	This register is the same as EVERR, except reading it does not clear its contents. This address is meant to be used in debug mode. The ARM platform OnCE may check this register value without modifying it.

47.8.14 Configuration Register (SDMAARM_CONFIG)

Address: 20E_C000h base + 38h offset = 20E_C038h

SDMAARM_CONFIG field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 DSPDMA	This bit's function is reserved and should be configured as zero. 0 - Reset Value 1 - Reserved
11 RTDOBS	Indicates if Real-Time Debug pins are used: They do not toggle by default in order to reduce power consumption. 0 RTD pins disabled 1 RTD pins enabled
10–5 Reserved	This read-only field is reserved and always has the value 0.
4 ACR	ARM platform DMA / SDMA Core Clock Ratio. Selects the clock ratio between ARM platform DMA interfaces (burst DMA and peripheral DMA) and the internal SDMA core clock. The frequency selection is determined separately by the chip clock controller. This bit has to match the configuration of the chip clock controller that generates the clocks used in the SDMA. 0 ARM platform DMA interface frequency equals twice core frequency 1 ARM platform DMA interface frequency equals core frequency
3–2 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

SDMAARM_CONFIG field descriptions (continued)

Field	Description
CSM	<p>Selects the Context Switch Mode. The ARM platform has a read/write access. The SDMA cannot modify that register. The value at reset is 3, which selects the dynamic context switch by default. That register can be modified at anytime but the new context switch configuration will only be taken into account at the start of the next restore phase.</p> <p>NOTE: The first call to SDMA's channel 0 Bootload script after reset should use static context switch mode to ensure the context RAM for channel 0 is initialized in the channel SAVE Phase. After Channel 0 is run once, then any of the dynamic context modes can be used.</p> <p>0 static 1 dynamic low power 2 dynamic with no loop 3 dynamic</p>

47.8.15 SDMA LOCK (SDMAARM_SDMA_LOCK)

Address: 20E_C000h base + 3Ch offset = 20E_C03Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SDMAARM_ONCE_STAT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–12 PST[3:0]	<p>The Processor Status bits reflect the state of the SDMA RISC engine. Its states are as follows:</p> <ul style="list-style-type: none"> • The "Program" state is the usual instruction execution cycle. • The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. • The "Debug" state means the SDMA is in debug mode. • The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In "Sleep" modes, no script is running (this is the RISC engine idle state). The "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). • The "in Sleep" states are the same as above except they do not have any corresponding channel: They are used when entering debug mode after reset. The reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. <p>0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Restore</p>
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an <code>rbuffer</code> command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	<p>This flag is raised when the OnCE is controlled from the ARM platform peripheral interface.</p> <p>0 The JTAG interface controls the OnCE. 1 The ARM platform peripheral interface controls the OnCE.</p>
6–3 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

SDMAARM_ONCE_STAT field descriptions (continued)

Field	Description
ECDR	<p>Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one of the EDR bits is set (the meaning of the encoding is given below). The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addra_cond, addrb_cond, and data_cond conditions. The value of those fields is given by the EDR bits.</p> <p>0 1 matched addra_cond 1 1 matched addrb_cond 2 1 matched data_cond</p>

47.8.20 OnCE Command Register (SDMAARM_ONCE_CMD)

Address: 20E_C000h base + 50h offset = 20E_C050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARM_ONCE_CMD field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value 0.
CMD	<p>Writing to this register will cause the OnCE to execute the command that is written. When needed, the ONCE_DATA and ONCE_INSTR registers should be loaded with the correct value before writing the command to that register. For a list of the OnCE commands and their usage, see OnCE and Real-Time Debug.</p> <p>NOTE: 7-15 reserved</p> <p>0 rstatus 1 dmov 2 exec_once 3 run_core 4 exec_core 5 debug_rqst 6 rbuffer</p>

47.8.21 Illegal Instruction Trap Address (SDMAARM_ILLINSTADDR)

Address: 20E_C000h base + 58h offset = 20E_C058h

SDMAARM_ILLINSTADDR field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
ILLINSTADDR	The Illegal Instruction Trap Address is the address where the SDMA jumps when an illegal instruction is executed. It is 0x0001 after reset. The value of ILLINSTADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.

47.8.22 Channel 0 Boot Address (SDMAARM_CHN0ADDR)

Address: 20E_C000h base + 5Ch offset = 20E_C05Ch

SDMAARM_CHN0ADDR field descriptions

Field	Description
31–15 Reserved	This read-only field is reserved and always has the value 0.
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context,

Table continues on the next page...

SDMAARM_CHN0ADDR field descriptions (continued)

Field	Description
	<p>which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism.</p> <p>The value of SMSZ cannot be changed if the LOCK bit in the SDMA_LOCK register is set.</p> <p>0 24 words per context 1 32 words per context</p>
CHN0ADDR	<p>This 14-bit register is used by the boot code of the SDMA. After reset, it points to the standard boot routine in ROM (channel 0 routine). By changing this address, you can perform a boot sequence with your own routine. The very first instructions of the boot code fetch the contents of this register (it is also mapped in the SDMA memory space) and jump to the given address. The reset value is 0x0050 (decimal 80).</p> <p>The value of CHN0ADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.</p>

47.8.23 DMA Requests (SDMAARM_EVT_MIRROR)

Address: 20E_C000h base + 60h offset = 20E_C060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARM_CHNENBLn field descriptions

Field	Description
ENBLn	This 32-bit value selects the channels that are triggered by the DMA request number <i>n</i> . If ENBLn[i] is set to 1, bit EP[i] will be set when the DMA request <i>n</i> is received. These 48 32-bit registers are physically located in a RAM, with no known reset value. It is thus essential for the ARM platform to program them before any DMA request is triggered to the SDMA, otherwise an unpredictable combination of channels may be started.

47.9 BP Memory Map and Control Register Definitions

The following section describes SDMA control registers available to the BP.

NOTE

These registers are physically implemented in all platforms, but are not accessible when the SDMA BP control port is not connected. Reset values are calculated to allow the system to work when those registers cannot be accessed.

All registers are clocked with the SDMA clock (which means the SDMA clock must be running when the BP wants to access any register).

SDMABP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Channel 0 Pointer (SDMABP_DC0PTR)	32	R/W	0000_0000h	47.9.1/3144
4	Channel Interrupts (SDMABP_INTR)	32	w1c	0000_0000h	47.9.2/3145
8	Channel Stop/Channel Status (SDMABP_STOP_STAT)	32	R/W	0000_0000h	47.9.3/3145
C	Channel Start (SDMABP_DSTART)	32	R	0000_0000h	47.9.4/3146
28	DMA Request Error Register (SDMABP_EVTERR)	32	R	0000_0000h	47.9.5/3146
2C	Channel DSP Interrupt Mask (SDMABP_INTRMASK)	32	R/W	0000_0000h	47.9.6/3147
34	DMA Request Error Register (SDMABP_EVTERRDBG)	32	R	0000_0000h	47.9.7/3147

47.9.1 Channel 0 Pointer (SDMABP_DC0PTR)

Address: 0h base + 0h offset = 0h

SDMABP_DC0PTR field descriptions

Field	Description
DC0PTR	Channel 0 Pointer contains the 32-bit address, in BP memory, of the array of channel control blocks starting with the one for channel 0 (the control channel). This register should be initialized by the BP before it enables a channel (for example, channel 0). See the API document SDMA Scripts User Manual for the use of this register. The BP has a read/write access and the SDMA has a read-only access.

47.9.2 Channel Interrupts (SDMABP_INTR)

Address: 0h base + 4h offset = 4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMABP_INTR field descriptions

Field	Description
DI	The BP Interrupts register contains the 32 DI[i] bits. If any bit is set, it will cause an interrupt to the BP. <ul style="list-style-type: none"> This register is a "write-ones" register to the BP. When the BP sets a bit in this register, the corresponding DI[i] bit is cleared. The interrupt service routine should clear individual channel bits when their interrupts are serviced; failure to do so will cause continuous interrupts. The SDMA is responsible for setting the DI[i] bit corresponding to the current channel when the corresponding <code>done</code> instruction is executed.

47.9.3 Channel Stop/Channel Status (SDMABP_STOP_STAT)

Address: 0h base + 8h offset = 8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DE																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMABP_STOP_STAT field descriptions

Field	Description
DE	This 32-bit register gives access to the BP (DSP) Enable bits, DE. There is one bit for every channel. <ul style="list-style-type: none"> This register is a "write-ones" register to the BP. When the BP writes 1 in bit <i>i</i> of this register, it clears the DE[i] and DSTART[i] bits. Reading this register yields the current state of the DE[i] bits.

47.9.4 Channel Start (SDMABP_DSTART)

Address: 0h base + Ch offset = Ch

SDMABP_DSTART field descriptions

Field	Description
DSTART_DE	<p>The DSTART_DE registers are 32 bits wide with one bit for every channel.</p> <ul style="list-style-type: none"> • When a bit is written to 1, it enables the corresponding channel. • Two physical registers are accessed with that address (DSTART and DE), which enables the BP to trigger a channel a second time before the first trigger was processed. • This register is a "write-ones" register to the BP. Neither DSTART[i] bit can be set while the corresponding DE[i] bit is cleared. • When the BP tries to set the DSTART[i] bit by writing a one (if the corresponding DE[i] bit is clear), the bit in the DSTART[i] register will remain cleared and the DE[i] bit will be set. If the corresponding DE[i] bit was already set, the DSTART[i] bit will be set. • The next time the SDMA channel <i>i</i> attempts to clear the DE[i] bit by means of a <code>done</code> instruction, the bit in the DSTART[i] register will be cleared and the DE[i] bit will take the old value of the DSTART[i] bit. • Reading this register yields the current state of the DSTART[i] bits. This mechanism enables the BP to pipeline two DSTART commands per channel.

47.9.5 DMA Request Error Register (SDMABP_EVTERR)

Address: 0h base + 28h offset = 28h

SDMABP_EVTERR field descriptions

Field	Description
CHNERR	<p>This register is used by the SDMA to warn the BP when an incoming DMA request was detected; it then triggers a channel that is already pending or being serviced, which may mean there is an overflow of data for that channel. An interrupt is sent to the BP if the corresponding channel bit is set in the INTRMASK register.</p> <ul style="list-style-type: none"> • This is a "write-ones" register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the BP or during an SDMA reset. • The CHNERR[i] bit is set when a DMA request that triggers channel <i>i</i> is received through the corresponding input pins and the EP[i] bit is already set. The EVTERR[i] bit is unaffected if the BP tries to set the EP[i] bit when that EP[i] bit is already set.

47.9.6 Channel DSP Interrupt Mask (SDMABP_INTRMASK)

Address: 0h base + 2Ch offset = 2Ch

SDMABP_INTRMASK field descriptions

Field	Description
DIMASK	The Interrupt Mask Register contains 32 interrupt generation mask bits. If bit DIMASK[i] is set, the DI[i] bit is set and an interrupt is sent to the BP when a DMA request error is detected on channel <i>i</i> (for example, EVTERR[i] is set).

47.9.7 DMA Request Error Register (SDMABP_EVTERRDBG)

Address: 0h base + 34h offset = 34h

SDMABP_EVTERRDBG field descriptions

Field	Description
CHNERR	This register is the same as EVTERR except reading it does not clear its contents. This address is meant to be used in debug mode. The BP OnCE may check this register value without modifying it.

47.10 SDMA Internal (Core) Memory Map and Internal Register Definitions

The actual SDMA memory mapped registers are summarized in the following sections; for peripherals' memory maps, refer to the respective chapters.

The following definitions serve as a key for the SDMA internal register summary.

SDMACORE memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
201_C000	ARM platform Channel 0 Pointer (SDMACORE_MC0PTR)	32	R	0000_0000h	47.10.1/3149
201_C008	Current Channel Pointer (SDMACORE_CCPTTR)	32	R	0000_0000h	47.10.2/3149
201_C00C	Current Channel Register (SDMACORE_CCR)	32	R	0000_0000h	47.10.3/3149
201_C010	Highest Pending Channel Register (SDMACORE_NCR)	32	R	0000_0000h	47.10.4/3150
201_C014	External DMA Requests Mirror (SDMACORE_EVENTS)	32	R	0000_0000h	47.10.5/3151
201_C018	Current Channel Priority (SDMACORE_CCPRI)	32	R	0000_0000h	47.10.6/3152
201_C01C	Next Channel Priority (SDMACORE_NCPRI)	32	R	0000_0000h	47.10.7/3152
201_C020	OnCE Event Cell Counter (SDMACORE_ECOUNT)	32	R/W	0000_0000h	47.10.8/3153
201_C024	OnCE Event Cell Control Register (SDMACORE_ECTL)	32	R/W	0000_0000h	47.10.9/3153
201_C028	OnCE Event Address Register A (SDMACORE_EAA)	32	R/W	0000_0000h	47.10.10/3155
201_C02C	OnCE Event Cell Address Register B (SDMACORE_EAB)	32	R/W	0000_0000h	47.10.11/3155
201_C030	OnCE Event Cell Address Mask (SDMACORE_EAM)	32	R/W	0000_0000h	47.10.12/3155
201_C034	OnCE Event Cell Data Register (SDMACORE_ED)	32	R/W	0000_0000h	47.10.13/3156
201_C038	OnCE Event Cell Data Mask (SDMACORE_EDM)	32	R/W	0000_0000h	47.10.14/3156
201_C03C	OnCE Real-Time Buffer (SDMACORE_RTB)	32	R/W	0000_0000h	47.10.15/3157
201_C040	OnCE Trace Buffer (SDMACORE_TB)	32	R	0000_0000h	47.10.16/3157
201_C044	OnCE Status (SDMACORE_OSTAT)	32	R	0000_0000h	47.10.17/3158
201_C048	Channel 0 Boot Address (SDMACORE_MCHN0ADDR)	32	R	0000_0000h	47.10.18/3160
201_C04C	ENDIAN Status Register (SDMACORE_ENDIANNES)	32	R	0000_0001h	47.10.19/3161
201_C054	Lock Status Register (SDMACORE_SDMA_LOCK)	32	R	0000_0000h	47.10.20/3162
201_C058	External DMA Requests Mirror #2 (SDMACORE_EVENTS2)	32	R	0000_0000h	47.10.21/3163

47.10.1 ARM platform Channel 0 Pointer (SDMACORE_MC0PTR)

Address: 201_C000h base + 0h offset = 201_C000h

SDMACORE_MC0PTR field descriptions

Field	Description
MC0PTR	Contains the address-in the ARM platform memory space-of the initial SDMA context and scripts that are loaded by the SDMA boot script running on channel 0.

47.10.2 Current Channel Pointer (SDMACORE_CCPtr)

Address: 201_C000h base + 8h offset = 201_C008h

SDMACORE_CCPtr field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
CCPtr	Contains the start address of the context data for the current channel: Its value is $CONTEXT_BASE + 24 * CCR$ or $CONTEXT_BASE + 32 * CCR$ where $CONTEXT_BASE = 0x0800$. The value 24 or 32 is selected according to the programmed channel scratch RAM size in the register shown in Channel 0 Boot Address (SDMAARM_CHN0ADDR) .

47.10.3 Current Channel Register (SDMACORE_CCR)

Address: 201_C000h base + Ch offset = 201_C00Ch

SDMACORE_CCR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
CCR	Contains the number of the current running channel whose context is installed. In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel. The PST bits in the OSTAT register indicate when the SDMA is in sleep state.

47.10.4 Highest Pending Channel Register (SDMACORE_NCR)

Address: 201_C000h base + 10h offset = 201_C010h

SDMACORE_NCR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
NCR	Contains the number of the pending channel that the scheduler has selected to run next.

47.10.5 External DMA Requests Mirror (SDMACORE_EVENTS)

NOTE

This register is very useful in the case of DMA requests that are active when a peripheral FIFO level is above the programmed watermark. The activation of the DMA request (rising edge) is detected by the SDMA logic and it can enable one or several channels. One of the channels accesses the peripheral and reads or writes a number of data that matches the watermark level (for example, if the watermark is four words, the channel reads or writes four words).

If the channel is effectively executed long after the DMA request was received, reading or writing the watermark number of data may not be sufficient to reset the DMA request (for example, if the FIFO watermark is four and at the channel execution it already contains nine pieces of data). This means no new rising edge may be detected by the SDMA, although there still remains transfers to perform. Therefore, if the channel were terminated at that time, it would not be restarted, causing potential overrun or underrun of the peripheral.

The proposed mechanism is for the channel to check this register after it has performed the "watermark" number of accesses to the peripheral. If the bit for the DMA request that triggers this channel is set, it means there is still another watermark number of data to transfer. This goes on until the bit is cleared. The same script can be used for multiple channels that require this behavior. The script can determine its channel number from the CCR register and infer the corresponding DMA request bit to check. It needs a reference table that is coherent with the request-channel matrix that the ARM platform programmed.

Address: 201_C000h base + 14h offset = 201_C014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE_EVENTS field descriptions

Field	Description
EVENTS	Reflects the status of the SDMA's external DMA requests. It is meant to allow any channel to monitor the states of these SDMA inputs. This register displays EVENTS 0-31. The EVENTS2 register displays events 32-47.

47.10.6 Current Channel Priority (SDMACORE_CCPRI)

Address: 201_C000h base + 18h offset = 201_C018h

SDMACORE_CCPRI field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
CCPRI	Contains the 3-bit priority of the channel whose context is installed. It is 0 when no channel is running. NOTE: 1-7 current channel priority 0 no running channel

47.10.7 Next Channel Priority (SDMACORE_NCPRI)

Address: 201_C000h base + 1Ch offset = 201_C01Ch

SDMACORE_NCPRI field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
NCPRI	Contains the 3-bit priority of the channel the scheduler has selected to run next. It is 0 when no other channel is pending.

47.10.8 OnCE Event Cell Counter (SDMACORE_ECOUNT)

Address: 201_C000h base + 20h offset = 201_C020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE_ECOUNT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
ECOUNT	The event cell counter contains the number of times minus one that an event detection must occur before generating a debug request. <ul style="list-style-type: none"> This register should be written before any attempt to use the event detection counter during an event detection process. The counter is cleared on a JTAG reset.

47.10.9 OnCE Event Cell Control Register (SDMACORE_ECTL)

Address: 201_C000h base + 24h offset = 201_C024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMACORE_ECTL field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
13 EN	Event Cell Enable. If the EN bit is set, the event cell is allowed to generate debug requests (the cell is awakened). If it is cleared, the event detection unit is disabled and no hardware breakpoint is generated, but matching conditions are still reflected on the emulation pin. <p>0 Cell is disabled. 1 Cell is enabled.</p>
12 CNT	Event Counter Enable. The event counter enable bit determines if the cell counter is used during the event detection. In order to use the event counter during an event detection process, the event cell counter register should be loaded with a value equal to the number of times minus one that an event occurs before

Table continues on the next page...

SDMACORE_ECTL field descriptions (continued)

Field	Description
	<p>a debug request is sent. After every event detection, the counter is decreased. When the counter reaches the value 0, the event detection cell sends a debug request to the core. The event counter register should be written and the EN bit should be set before each new event detection process uses the event counter.</p> <p>0 Counter is disabled. 1 Counter is enabled.</p>
11–10 ECTC[1:0]	<p>The event cell trigger condition bits select the combination of address and data matching conditions that generate the final address/data condition. During program execution, if this event cell trigger condition goes to 1, a debug request is sent to the SDMA. The EN bit must be set to enable the debug request generation.</p> <p>00 address ONLY 01 data ONLY 10 address AND data 11 address OR data</p>
9–8 DTC[1:0]	<p>The data trigger condition bits define when data is considered matching after comparison with the data register of the event detection unit. The operations are performed on unsigned values.</p> <p>00 equal 01 not equal 10 greater than 11 less than</p>
7–6 ATC[1:0]	<p>The address trigger condition bits select how the two address conditions (addressA and addressB) are combined to define the global address matching condition. The supported combinations are described, as follows.</p> <p>00 addressA ONLY 01 addrA AND addrB 10 addrA OR addrB 11 reserved</p>
5–4 ABTC[1:0]	<p>The Address B Trigger Condition (ABTC) controls the operations performed by address comparator B. All operations are performed on unsigned values. This comparator B outputs the addressB condition.</p> <p>00 equal 01 not equal 10 greater than 11 less than</p>
3–2 AATC[1:0]	<p>The Address A Trigger Condition (AATC) controls the operations performed by address comparator A. All operations are performed on unsigned values. This comparator A outputs the addressA condition.</p> <p>00 equal 01 not equal 10 greater than 11 less than</p>
ATS[1:0]	<p>The access type select bits define the memory access type required on the SDMA memory bus.</p> <p>00 read ONLY 01 write ONLY 10 read or write 11 -</p>

47.10.10 OnCE Event Address Register A (SDMACORE_EAA)

Address: 201_C000h base + 28h offset = 201_C028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE_EAM field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
EAM	The Event Cell Address Mask contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before performing the address comparison. NOTE: There is a common address mask value for both address comparators. If bit <i>i</i> of this register is set, then bit <i>i</i> of the address value latched from the memory bus does not influence the result of the address comparison. The register is cleared on a JTAG reset.

47.10.13 OnCE Event Cell Data Register (SDMACORE_ED)

Address: 201_C000h base + 34h offset = 201_C034h

SDMACORE_ED field descriptions

Field	Description
ED	The event cell data register contains a user defined data value. This data value is an input for the data comparator which generates the data condition. It is cleared on a JTAG reset.

47.10.14 OnCE Event Cell Data Mask (SDMACORE_EDM)

Address: 201_C000h base + 38h offset = 201_C038h

SDMACORE_EDM field descriptions

Field	Description
EDM	The event cell data mask register contains the user-defined data mask value. <ul style="list-style-type: none"> This mask is applied to the data value latched from the memory bus before performing the data comparison. Setting bit <i>i</i> of the event cell data mask register means that bit <i>i</i> of the data value latched from the address bus does not influence the result of the data comparison. The data mask is cleared on a JTAG reset.

47.10.15 OnCE Real-Time Buffer (SDMACORE_RTb)

Address: 201_C000h base + 3Ch offset = 201_C03Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE_OSTAT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–12 PST[3:0]	<p>The Processor Status bits reflect the state of the SDMA RISC engine.</p> <ul style="list-style-type: none"> The "Program" state is the usual instruction execution cycle. The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel-switching instructions). The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. The "Debug" state means the SDMA is in debug mode. The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). In "Sleep" modes, no script is running (this is the RISC engine idle state). The "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). The "in Sleep" states are the same as above except they do not have any corresponding channel. They are used when entering debug mode after reset; the reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. <p>0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow Loop Sleep 12 Debug in Sleep 13 Functional Unit in Sleep</p>

Table continues on the next page...

SDMACORE_OSTAT field descriptions (continued)

Field	Description
	14 Sleep after Reset 15 Restore
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an <code>rbuffer</code> command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	This flag is raised when the OnCE is controlled from the ARM platform peripheral interface. 0 JTAG interface controls the OnCE. 1 ARM platform peripheral interface controls the OnCE.
6–3 Reserved	This read-only field is reserved and always has the value 0.
ECDR[2:0]	Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addressA, addressB, and data conditions; the value of those fields is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one EDR bit is set; the meaning of the encoding is as follows: 0 1 matched addressA condition 1 1 matched addressB condition 2 1 matched data condition

47.10.18 Channel 0 Boot Address (SDMACORE_MCHN0ADDR)

Address: 201_C000h base + 48h offset = 201_C048h

SDMACORE_MCHN0ADDR field descriptions

Field	Description
31–15 Reserved	This read-only field is reserved and always has the value 0.
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context, which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism. 0 24 words per context 1 32 words per context
CHN0ADDR[13:0]	Contains the address of the channel 0 routine programmed by the ARM platform; it is loaded into a general register at the very start of the boot and the SDMA jumps to the address it contains. By default, it points to the standard boot routine in ROM.

47.10.19 ENDIAN Status Register (SDMACORE_ENDIANNES)

Address: 201_C000h base + 4Ch offset = 201_C04Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W	[Reserved]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												0		APEND	
W	[Reserved]												[Reserved]		[Reserved]	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

SDMACORE_ENDIANNES field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
2–1 Reserved	This read-only field is reserved and always has the value 0.
0 APEND	APEND indicates the endian mode of the Peripheral and Burst DMA interfaces. This bit is tied to logic '1' indicating little-endian mode. 0 - ARM platform is in big-endian mode 1 - ARM platform is in little-endian mode

47.10.20 Lock Status Register (SDMACORE_SDMA_LOCK)

Address: 201_C000h base + 54h offset = 201_C054h

SDMACORE_SDMA_LOCK field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value 0.
0 LOCK	The LOCK bit reports the value of the LOCK bit in the SDMA_LOCK status register. SDMA software may use this value to determine if certain operations such as loading of new scripts is allowed. 0 - LOCK bit clear 1 - LOCK bit set

47.10.21 External DMA Requests Mirror #2 (SDMACORE_EVENTS2)

Address: 201_C000h base + 58h offset = 201_C058h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
R	0																EVENTS																	
W	[Shaded]																																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		

SDMACORE_EVENTS2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
EVENTS	Reflects the status of the SDMA's external DMA requests. It is meant to allow any channel to monitor the states of these SDMA inputs. This register displays EVENTS 32-47. The separate EVENTS register displays events 0-31.

47.11 SDMA Peripheral Registers

Refer to the respective peripherals' chapters for more information.

Chapter 48

System JTAG Controller (SJC)

48.1 Overview

The System JTAG Controller (SJC) provides debug and test control with the maximum security.

The test access port (TAP) is designed to support features compatible with the IEEE Standard 1149.1 v2001 (JTAG).

The figure below shows an overview of the JTAG architecture.

Figure 48-1. System JTAG Controller (SJC) Block Diagram

48.1.1 Features

The System JTAG Controller (SJC) provides the following capabilities:

- JTAG IEEE1149.1 mandatory instructions, see [EXTEST Instruction](#), [SAMPLE/PRELOAD Instruction](#), and [BYPASS Instruction](#).
- JTAG IEEE1149.1 optional instructions, see [ID_CODE Instruction \(IDCODE\)](#), and [HIGHZ Instruction](#).
- JTAG IEEE P1149.1 (standard JTAG) interface to off-chip test and development equipment including an SJC-only mode for true IEEE 1149.1 compliance, used primarily for board-level implementation of boundary scan.

- IEEE P1149.6 (JTAG) mandatory instructions, see [EXTEST_PULSE instruction](#) and [EXTEST_TRAIN instruction](#). These two instructions enable edge-detecting behavior on the signal path containing AC pins.
- Debug-related control and status, such as putting selected cores into reset and/or debug mode and the ability to monitor individual core status signals via JTAG.
- Provides means for accessing each OnCE/ICE TAP controller independently to control a target system (see [Modes of Operation](#)).
- ExtraDebug logic (see [ENABLE_ExtraDebug Instruction](#)).
- The maximum clock speed of the SJC is one-eighth of the lowest frequency of the accessed OnCE/ICE. For example in normal operation (no core in low-power mode), this frequency is one-eighth of the SDMA frequency if this core is present in the TDI-TDO chain (serially connected with other cores or standalone). The user must also consider the 25 MHz frequency limitation on the CE bus.
- Core compliant modes to support standalone core debuggers (see [Modes of Operation](#)).
- Multi-cores daisy chained mode (default one) to support multi-core debuggers (see [Modes of Operation](#)).

Detailed information about the SJC is provided in the Security Reference Manual. Contact your Freescale representative for information about obtaining this document.

48.1.2 Modes of Operation

The SJC modes are controlled through both the TAP select register (SJC_TSR) and the MOD input port.

The MOD port (typically connected to pad of the same name) selects between two possible topologies of TAP connections, as seen at SoC level:

- Negating it (this should be the default state) selects all the TAPs (SJC, SDMA, DAP and ARM/ETM) to be connected in the TDI-TDO chain, which is referred to as "daisy chain" mode, throughout this chapter.
- Asserting it only selects the SJC TAP to be connected in the TDI-TDO chain.

IEEE1149.1 standard features are enabled by configuring the SJC input pin: MOD. Refer to the following table for MOD settings details:

Table 48-1. SJC Modes

MOD	Name	Description
0	Daisy chain ALL	For common SW debug (High speed and production)
1	SJC only	IEEE 1149.1 JTAG compliant mode

The following figure shows the SJC mode selection flow. The numbers shown in parenthesis below each block name indicates the TAP's IR length.

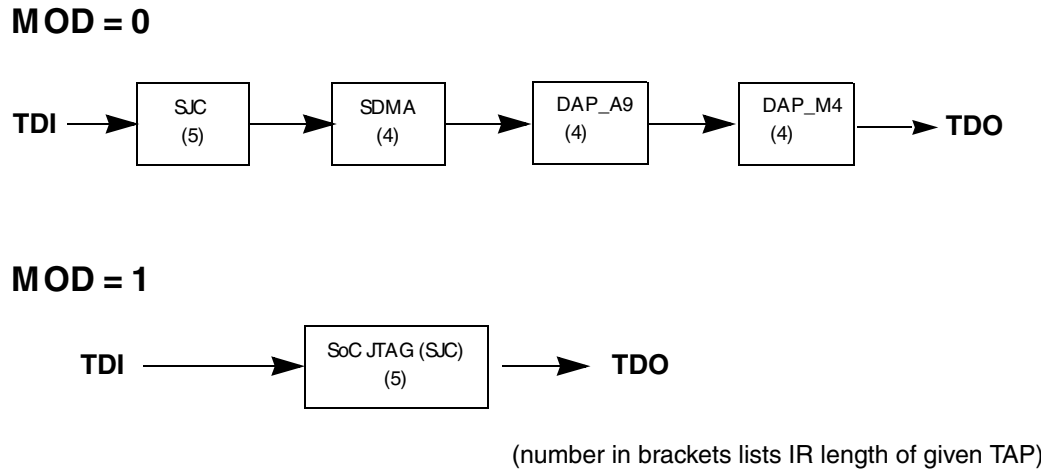

Figure 48-2. SJC Mode Selection Using MOD Pin Sampling

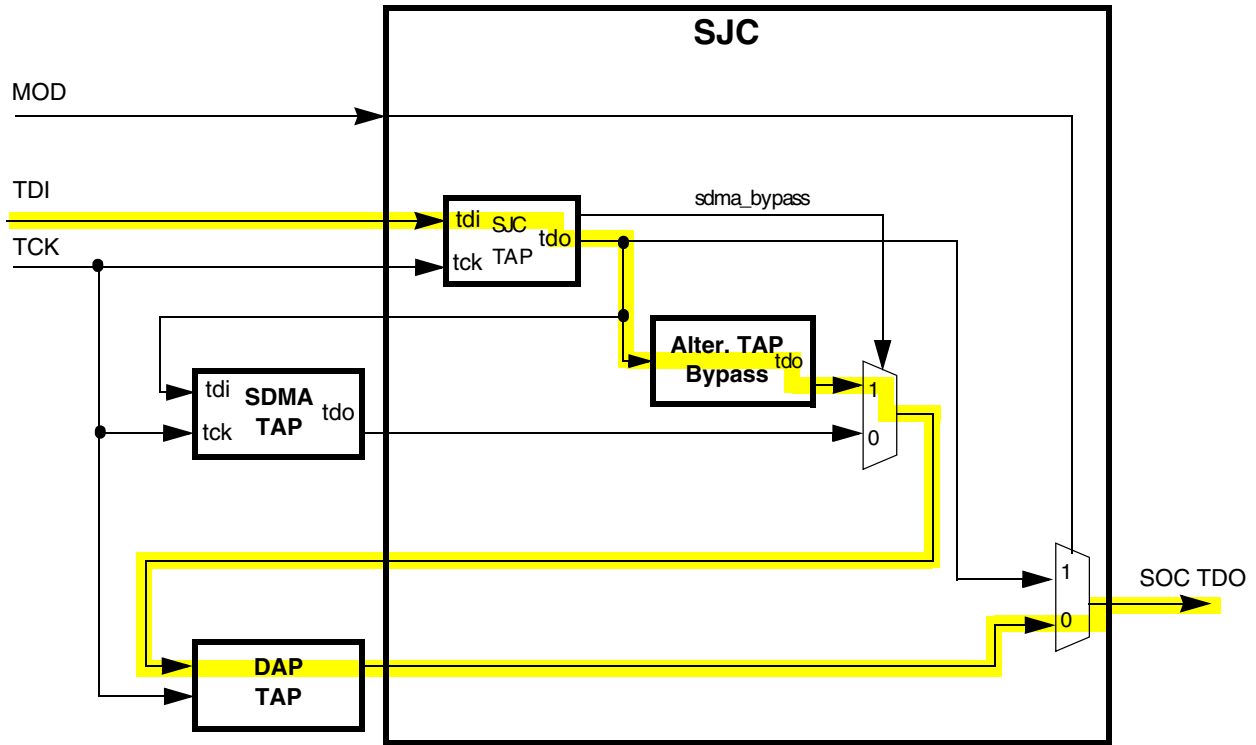

The Connect SDMA bit inside TAP select register controls the SDMA TAP bypass.

- When negated (should be the default state), the SDMA TAP is bypassed with a single D-FF (Flip-flop) during Shift-Dr path
- When asserted SDMA TAP is connected inside the chain
- When taking the SDMA into bypass or out of bypass (by writing to tapsel reg), additional cycle with TMS '0' should be given

The TAP selection block (TSB) provides a simple method of integrating various pieces of IP that have embedded TAPs.

- Provides a way to connect up multiple TAPs within a single SoC
- Identify the SJC TAP as the master TAP which controls the boundary chain (for IEEE 1149.1 standard compliance)
- Follow the state of SJC TAP, and when the Test-Logic-Reset (TLR) state is reached, reset all TAPs

The figure below shows the TAP Selection Block and SOC TAP Chain Scheme.

Note: The default daisy chain connectivity is highlighted in yellow

Figure 48-3. TAP Selection Block and SoC TAP Chain Scheme

NOTE

It is the responsibility of the user to ensure that in any configuration of the TAP controllers chosen, all of the TAPs in the chain comply with the demands of TCK clock frequency as well as the required ratio between TCK clock frequency and that of the core's to which the TAP refers.

48.2 External Signals

The table found here describes the external signals of SJC.

Table 48-2. SJC External Signals

Signal	Description	Pad	Mode	Direction
JTAG_DE_B	SoC debug request/acknowledge pin. The DE_IN_B pin is used to propagate an external debug request event to the core(s). This functionality must be enabled first, by set of DE_to_ARM /	UART2_CTS_B	ALT7	IO

Table continues on the next page...

**Table 48-2. SJC External Signals
(continued)**

Signal	Description	Pad	Mode	Direction
	DE_to_SDMA bits in SJC's DCR register. It is SoC implementation dependent, whether this pin can also be used to reflect the debug acknowledge event back from the cores (in the case where an Open-Drain scheme is used externally).			
JTAG_MOD	SJC mode selection. This pin is sampled at TRST reset to determine two possible modes for the TAP connection configuration.	JTAG_MOD	No muxing	I
JTAG_TCK	Test Clock (TCK). This is used to synchronize the test logic and includes an internal pull-up resistor	JTAG_TCK	ALT0	I
JTAG_TDI	Test Data Input (TDI). Serial test instruction and data are received through the test data input (TDI) pin. TDI is sampled on the rising edge of TCK and includes an internal pullup resistor	JTAG_TDI	ALT0	I
JTAG_TDO	Test Data Output (TDO). The serial output for test instructions and data. TDO is tri-statable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK	JTAG_TDO	ALT0	O
JTAG_TMS	Test Mode Select (TMS). This is used to sequence the test controller's state machine. TMS is sampled on the rising edge of TCK and includes an internal pullup resistor	JTAG_TMS	ALT0	I
JTAG_TRSTB	Test Reset (TRST). This is used to asynchronously initialize the test controller. The TRST pin has an internal pullup resistor	JTAG_TRST_B	ALT0	I

48.2.1 External Signal Overview

The SJC provides test and debug control with a minimum number of contacts.

The figure below shows SJC connections to external contacts and other chip blocks.

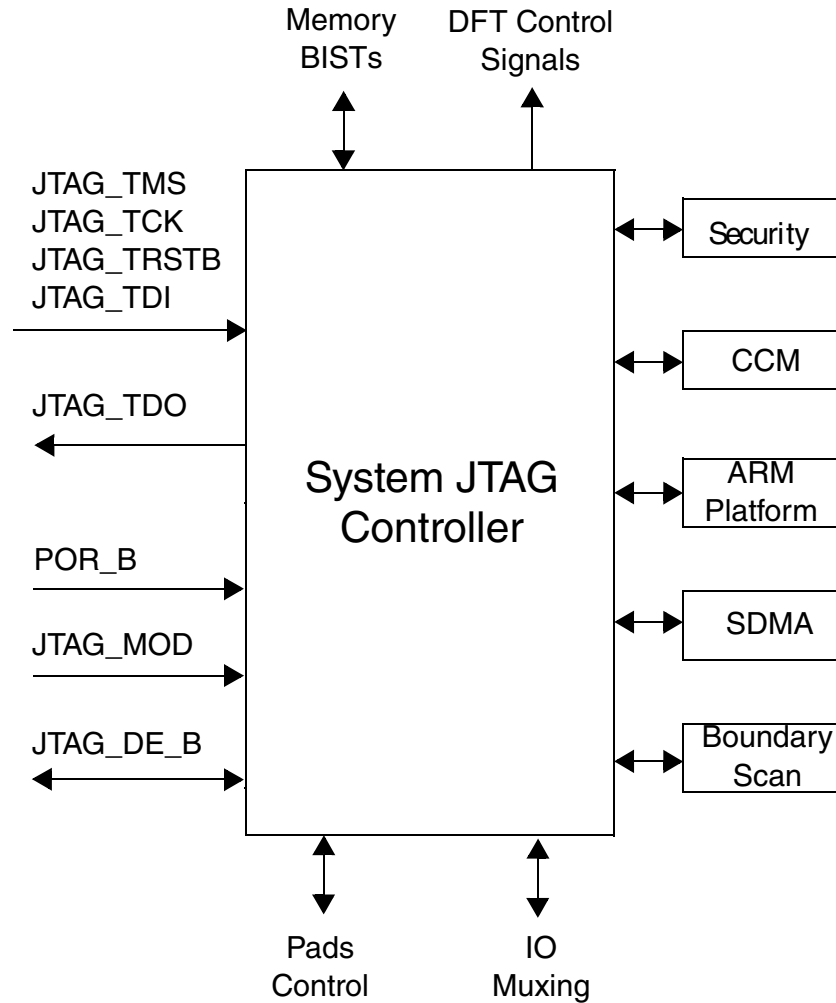

Figure 48-4. SJC Connections

48.2.2 TAP Controller

The TAP controller is responsible for interpreting the sequence of logical values on the TMS signal. It is a synchronous state machine that controls the operation of the JTAG logic. The value shown adjacent to each arc represents the value of the TMS signal sampled on the rising edge of TCK signal. For a description of the TAP controller states, refer to the appropriate IEEE 1149.1 document.

The state machine is shown in the following figure.

Figure 48-5. TAP Controller State Machine

The change of the JTAG state machine occurs on the rising edge of TCK. TMS and TDI change on the falling edge of TCK. TDO also changes on the falling edge of TCK following entry into the Shift_DR or Shift_IR states (TDO_EN is the enable of the tristate buffer driving the TDO output).

The figure below shows the timings of the SJC signals.

Figure 48-6. SJC Signals Timing Diagram

48.2.3 Accessing ExtraDebug Registers

Accessed through the Select-DR-Scan path, the ExtraDebug shift register consists of 38 bits (maximum) comprising a 32-bit data field (max length, see extradebug register description), a 5 bit address field and read/write bit.

The write actually takes place when the JTAG TAP controller enters the Update-DR state. On a read, the data field is ignored (the user should shift only 5 times to enter Read=1 and the address), the read takes place on the next path through DR at the Capture-DR state, the data is shifted-out during the Shift-DR state.

On the second path for a read access, simultaneous write access is not supported: command converter software shifts in zeros so the TAP decodes a write to the CSR (read-only register) which does not have any effect on the circuit.

The number of shift depends on the width of the accessed register as explained in the following diagrams.

First a write access (one path through Select-DR-Scan):

Figure 48-7. TDI/TDO on write access

Then a read access (requires two paths through Jtag DR Scan path):

First path

Second path

Figure 48-8. TDI/TDO on Read Access

For example, write value 0b1010_1100 to Debug Control Register (address = 0b00110).

Figure 48-9. Example: Write Access to DCR

The SJC registers have different levels of security (Refer to [JTAG Security Modes](#)):

- Secured- accessible only in mode 2 (supposed correct response entered), mode 3 and mode 4.
- Unsecured- accessible in all modes

The level of security of each register is indicated in its name or description, in "Programmable Registers" section.

A single DE_B pin is dedicated for debug request input/output in bidirectional open drain functionality (including an internal pull-up device).

Bits 6:5 in DCR register serve as mask bits, controlling the propagation of external debug request to each recipients (ARM Platform, SDMA).

The bits 1:0 define the propagation enable of IR debug request to recipient cores.

Figure 48-10. DE_B Pin Select Logic

For security reasons, bits for output and input propagation control are at their negated values after reset. A user cannot put the cores in debug mode through DE_B without any Jtag access.

The configuration after reset prevents propagation of debug requests / acknowledges to or from the cores.

48.3 TAP Selection Block (TSB)

As described in [Modes of Operation](#), the SJC can access cores in different modes selected through a TSB.

48.3.1 Select Mode Using Software

Conceptually, the SJC_TSR is a data register which is accessed through Access TSR IR instruction of SJC TAP.

The following figure shows the process of using reserved IR to access the SJC_TSR.

Figure 48-11. Using Reserved IR to Access the TAP Select Register (SJC_TSR)

The SJC_TSR can only be changed during the update-DR state of the TSB JTAG state machine. This is necessary to prevent a TAP that is being selected from losing synchronization with the TSB state machine when the TSB state machine returns to run-test-idle. Therefore, an associated shift register for the SJC_TSR is loaded into the SJC_TSR during the update-DR state (see the figure above). The shift register must also capture the state of the SJC_TSR when in the Capture-DR state for visibility of the contents of the SJC_TSR. See [TAP Select Instruction](#) , for more information.

48.4 Boundary Scan Register (BSR)

The Boundary Scan Register (BSR) in the JTAG implementation contains bits for all device signal and clock pins and associated control signals.

All SoC bidirectional pins have a single register bit in the boundary scan register for pin data, and are controlled by an associated control bit in the boundary scan register.

48.5 SoC JTAG Instruction Register (SJIR)

The SoC JTAG Instruction register is provided in the following table. The SoC JTAG Instruction register is 5 bits wide.

Table 48-3. SoC JTAG Instruction Register (SJIR)

Code					SJC IR
B4	B3	B2	B1	B0	
0	0	0	0	0	IDCODE
0	0	0	0	1	SAMPLE/PRELOAD
0	0	0	1	0	EXTEST
0	0	0	1	1	HI-Z
0	0	1	0	0	ENABLE_ExtraDebug
0	0	1	0	1	ENTER_DEBUG (secured)
0	0	1	1	0	Reserved
0	0	1	1	1	TAP select
0	1	0	0	0	EXTEST_PULSE
0	1	0	0	1	EXTEST_TRAIN
0	1	0	1	0	Reserved
0	1	0	1	1	Reserved
0	1	1	0	0	Security Output challenge
0	1	1	0	1	Security Enter response
-	-	-	-	-	Reserved
1	1	1	1	1	BYPASS

The instruction register is reset to 0b00000 in the test-logic-reset controller state which is equivalent to the IDCODE instruction.

During the capture-IR controller state, the parallel inputs to the instruction register are loaded with the code 01 in the least significant bits as required by the standard; the most significant bits are loaded with the values 00, leading to a capture value of 0b00001.

48.5.1 ID_CODE Instruction (IDCODE)

Selects the ID register, and the system logic controls the I/O pins. This instruction is provided as a public instruction to allow the manufacturer, part number and version of a component to be determined through the TAP.

The table below shows the ID register configuration.

Table 48-4. ID Configuration Register (IDCODE)

IDCODE				ID Configuration Register													
	BIT 31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	BIT 16	
	Version Information[3:0]			Part Number (Bits 27-16)													
TYPE	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	
RESET	0	0	0	0	x	x	x	x	x	x	x	x	x	x	x	x	
Note:																	
	BIT 15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	BIT 0	
	Part Number (Bits 15-12)				Manufacturer Identity											1	
TYPE	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	
RESET	x	x	x	x	0	0	0	0	0	0	0	1	1	1	0	1	
Note:																	

Table 48-5. ID Configuration Register Description (IDCODE)

Field	Description
31-28 Version Information	IC/SoC Version information number. Initial value: '0000' This number is subject to changes, for new IC/SoC (System On A Chip) revision releases.
27-12 Part Number	Customer Part Number The 16-bit Part Number value is unique for every Freescale's SoC / IC. See System Debug chapter for exact register value for a specific SoC.
11-1 Manufacturer Identity	Manufacturer Identity Freescale's Manufacturer Identity code. Bits [11:1] - 00000001110
0	Tied to logic 1.

One application of the ID register is to distinguish the manufacturer(s) of components on a board when multiple sourcing is used. As more components emerge which conform to the IEEE 1149.1 standard, it is desirable to allow for a system diagnostic controller unit to blindly interrogate a board design to determine the type of each component in each location. This information is also available for factory process monitoring and for failure mode analysis of assembled boards.

Once the IDCODE instruction is decoded, it selects the ID register which is a 32 Bit data register. Because the bypass register loads a logic 0 at the start of a scan cycle, whereas the ID register loads a logic 1 into its least significant bit, examination of the first bit of data shifted out of a component during a test data scan sequence immediate following exit from Test-Logic-Reset controller state shows whether such a register is included in the design. When the IDCODE instruction is selected, the operation of the test logic has no effect on the operation of the on-chip system logic as required by the IEEE 1149.1 standard.

48.5.2 SAMPLE/PRELOAD Instruction

Selects the boundary scan register and the system logic controls the I/O pins.

The SAMPLE/PRELOAD instruction provides two separate functions:

- First, it provides a means to obtain a snapshot of system data and control signals. The snapshot occurs on the rising edge of TCK in the capture-DR controller state. The data can be observed by shifting it transparently through the boundary scan register.
- The second function of SAMPLE/PRELOAD is to initialize the boundary scan register output cells prior to selection of EXTEST. This initialization ensures that known data appears on the outputs when entering the EXTEST instruction.

NOTE

Because there is no internal synchronization between the JTAG clock (TCK) and the system clock (CLK), the user must provide some form of external synchronization to achieve meaningful results.

For more details on the function and use of SAMPLE/PRELOAD, refer to the appropriate IEEE 1149.1 document.

48.5.3 EXTEST Instruction

Selects the boundary scan register, and the 1149.1 test logic has control of the I/O pins.

By using the TAP controller, the register is capable of:

- Scanning user-defined values into the output buffers,
- Capturing values presented to input pins
- Controlling the direction of bidirectional pins,
- Controlling the output drive of tri-statable output pins.

For more details on the function and use of EXTEST, refer to the appropriate IEEE 1149.1 document.

The EXTEST instruction also asserts internal reset for the cores (through CCM, refer to [Figure 48-14](#)) to force a predictable internal state while performing external boundary scan operations.

48.5.4 HIGHZ Instruction

All output drivers, including the two-state drivers, are turned off (that is, high impedance). The instruction selects the bypass register.

In this mode, all internal pullup resistors on all the pins (except for the TMS, TDI, TCK, TRSTB pins) are disabled. This disabling functionality is not built into SJC, but should be implemented by some logic in the SOC/IO Pads.

For more details on the function and use of HIGHZ, refer to the IEEE 1149.1 document.

The HIGHZ instruction also asserts internal reset for the cores (through CCM, refer to [Figure 48-14](#)) to force a predictable internal state while performing external boundary scan operations.

48.5.5 BYPASS Instruction

Selects the single Bit bypass register and the system logic controls the I/O pins.

This creates a shift-register path from TDI to the bypass register and, finally, to TDO, circumventing the boundary scan register. This instruction is used to enhance test efficiency when a component other than the SoC Core based device becomes the device under test.

When the bypass register is selected by the current instruction, the shift-register stage is set to a logic zero on the rising edge of TCK in the capture-DR controller state. Therefore, the first bit to be shifted out after selecting the bypass register is always a logic zero.

For more details on the function and use of BYPASS, refer to the appropriate IEEE 1149.1 document.

48.5.6 ENABLE_ExtraDebug Instruction

The TDI and TDO pins are connected directly to the ExtraDebug registers, the SJC TAP controller remaining connected to TDI and TMS.

The ExtraDebug shift register consists of 38 bits (maximum) comprising a 32-bits data field (maximum length, see [Accessing ExtraDebug Registers](#)), a 5 bits address field and read/write bit. On a register read, the data field does not need to be filled in. The particular ExtraDebug register connected between TDI and TDO at a given time is selected by the ExtraDebug controller depending on the ExtraDebug Address being currently decoded. All communication with the ExtraDebug controller is done through the Select-DR-Scan path of the JTAG TAP Controller.

48.5.7 ENTER_DEBUG instruction

The ENTER_DEBUG instruction is used to generate a debug request event to SDMA and the ARM Core Platform simultaneously (practically, inherited minimal skew is expected, due to difference in event signal propagation in the different modules).

The TDI and TDO are connected to the Instruction Register (IR). After the acknowledgment of the Debug Mode is received (can be checked by reading the Core Status Register part of the ExtraDebug logic), the user can perform system debug functions on the cores.

NOTE

The ENTER_DEBUG event issue to the cores, can be masked, by bits in DCR register.

NOTE

It is user's responsibility to shift-in another IR value (like IDCODE) before trying to bring the cores out of debug mode, as the debug request signals to the cores remains asserted as long as ENTER_DEBUG IR is in place.

NOTE

The user need to check that cores are in debug mode (watching debug acknowledge signal) before leaving ENTER_DEBUG instruction, otherwise debug request might not take affect.

48.5.8 TAP Select Instruction

By means of TAP select instruction a user can access TAP select register and by controlling its only bit SDMA Bypass, control whether SDMA TAP is bypassed or not.

Table 48-6. TAP Select Register (TSR)

	TAP Select Register
	BIT 0
	Connect SDMA
TYPE	rw
RESET	0
Note:	

Table 48-7. TAP Select Register Description

Field	Description
0 SDMA Bypass	Connect SDMA Control whether SDMA TAP is bypassed or not: <ul style="list-style-type: none"> • 0 - SDMA TAP is bypassed by the alternate TAP inside SJC (emulating 4-bit IR and 1-bit bypass path). • 1 - SDMA TAP is connected to the TDI-TDO chain. <p>NOTE: Additional cycle with TMS '0' should be inserted, after writing to this register, to allow the SDMA tap be sync before SDMA get into / out of bypass.</p>

48.5.9 EXTEST_PULSE instruction

The EXTEST_PULSE instruction implements test behaviors for AC pins and simultaneously behaves identically to IEEE Std 1149.1 EXTEST for DC pins.

48.5.10 EXTEST_TRAIN instruction

The EXTEST_TRAIN instruction implements test behaviors for AC pins and simultaneously behaves identically to IEEE Std 1149.1 EXTEST for DC pins.

48.6 Security

JTAG manipulation is one of the known hackers' ways of executing unauthorized program code, getting control over the OS and run code in privileged modes.

The SJC provides a debug access to several H/W blocks including the ARM processor and the system bus. This allows for program control and manipulation as well as visibility into system peripherals and memory. The ETM and NEXUS interfaces allow bus transactions to be traced. Together these tools provide the hacker all the access needed to completely comprise the system. Means must be provided to block any malicious JTAG access.

The SJC provides a way of regulating the JTAG access.

The following are the different JTAG security modes:

- **Mode #1: No Debug**-Maximum Security. All security sensitive JTAG features are permanently blocked.
- **Mode #2: Secure JTAG**-High security. JTAG use is regulated by secret key based authentication mechanism.
- **Mode #3: JTAG Enabled**-Low security. JTAG always enabled.

The JTAG security modes are configured using eFUSES which can be burned after packaging by applying electrical signals. The fuse burning is an irreversible process, once a fuse is burned (e-fuse or laser fuse) it is impossible to change the fuse back to the un-burned state.

48.6.1 JTAG Security Modes

JTAG can be in one of JTAG security modes which is selected by setting the SJC eFUSE configuration. The physical location of the fuses is not in the SJC.

48.6.1.1 Mode 1: No Debug - Maximum Security

No Debug JTAG security mode provides the highest security level.

In this mode, all JTAG features are disabled except for:

- ScanBoundary Scan
- MBIST, all modes except for debug modes which enable controlled memory contents output
- PLL BIST
- BIST monitor mode, allowing routing to external pins BIST pass/fail/invoke information
- PLL bypass- Bypass ARM or/and USB PLL.
- Visibility of the following status bits: power mode - normal, standby, stop, shutdown, and so on

These features do not reduce the security level of the product, and they allows to perform important tests and board connectivity checks.

48.6.1.2 Mode 2: Secure JTAG - High Security

The Secure JTAG mode limits the JTAG access by using challenge/response based authentication mechanism. Any access to JTAG port is being checked. Only authorized debug devices (that is, devices having the right response) can access the JTAG, unauthorized JTAG access attempts are denied.

The intent of this mode is to allow return field testing. When a secured JTAG device is being returned for debugging, this mode allows authorized re-activation of the JTAG.

48.6.1.2.1 Challenge/Response Mechanism in System JTAG Mode

When SJC is in Sysytem JTAG mode the authentication process is as follows:

1. Shift Output Challenge instruction to IR.
2. Passing through Capture-DR state of the SJC and by performing Shift-DR operations Challenge code can be accessed from TDO.
3. Shift Enter Response instruction to IR. By performing Shift-DR, operations enter Response code value through TDI. As Update-DR state is entered, Response code is compared with the correct one.

In Fixed challenge-response pair mode, each part has its individual challenge - response pair which is determined at manufacturing time, and does not change later on. The SJC compares the user's response to the expected response.

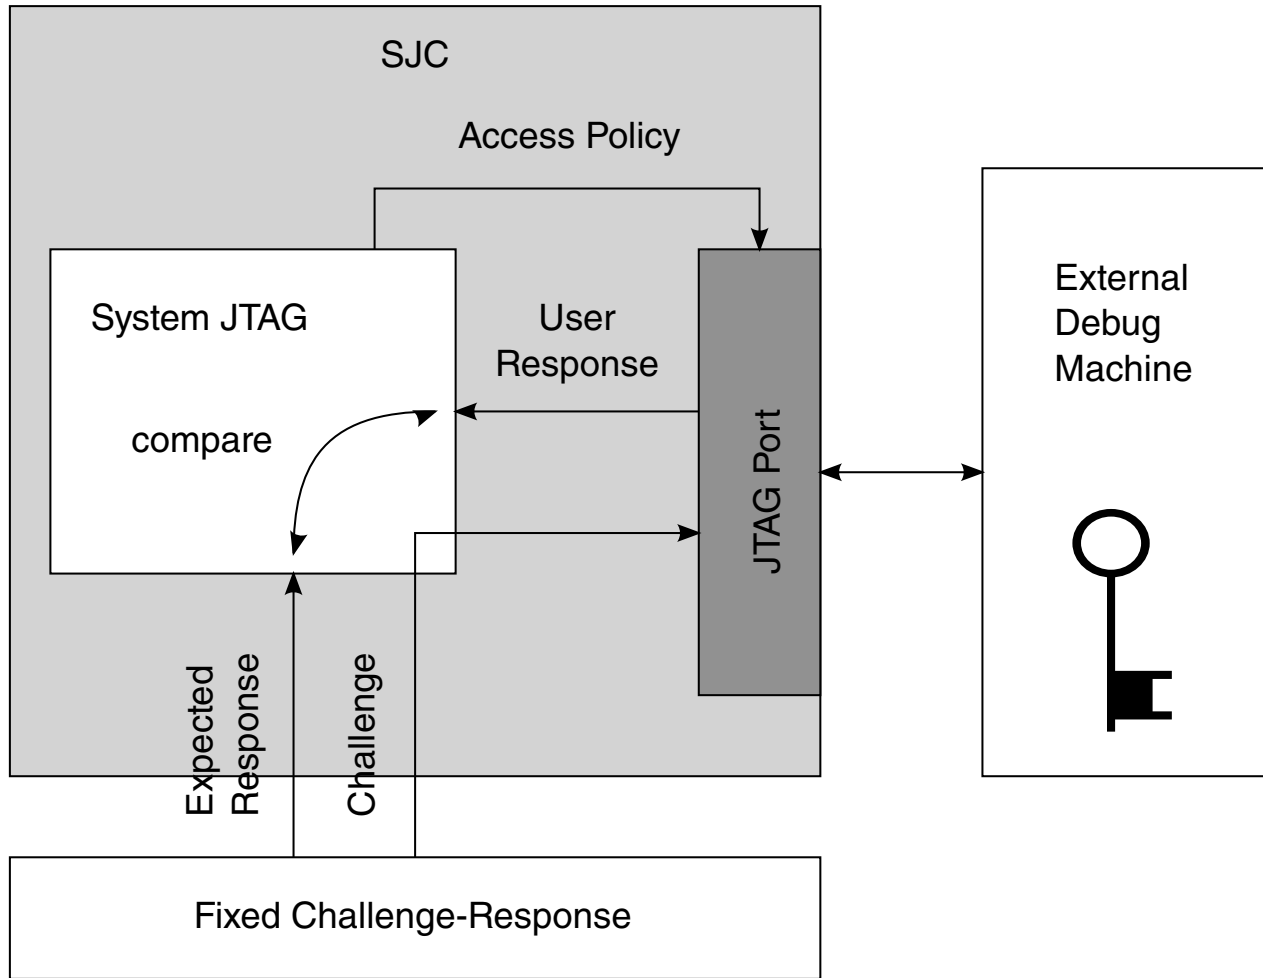

Figure 48-12. Mode #2 - Secure JTAG with Fixed Challenge-response Pair

48.6.1.3 Mode 3: JTAG Enabled - Low Security

In the JTAG Enabled JTAG security mode, all JTAG features are enabled.

48.6.2 Software Enabled JTAG

To increase the flexibility of the SJC, an option to enable the JTAG via software is added and is available only in Secure JTAG mode. By writing '1' to HAB_JDE (HAB JTAG DEBUG ENABLE) bit in the e-fuse controller module, the JTAG is opened, regardless of its security mode. It is the responsibility of software to assert or negate this bit.

Additionally, a corresponding lock bit is available (in the e-fuse control module) to ensure that only trusted software is able to set the JDE bit. When the LOCK bit is set, no future change of JDE is possible, until the next POR (power-on-reset) cycle.

The platform initialization software should set the LOCK bit for JDE bit before transferring control to the application code.

The S/W JTAG enable allows JTAG enabling without activating the challenge-Response mechanism (which requires JTAG access tool enhancement or special H/W). The JTAG S/W enable does not allow debug in case of boot or memory fault as it requires reset before entering debug.

This feature can be permanently blocked by burning the dedicated e-fuse.

NOTE

The S/W enabled JTAG feature reduces the overall security level of the system as it relies on S/W protections. If this feature is not required, it is strongly recommended to burn the JTAG_HEO e-fuse which disables this feature.

48.6.3 Kill Trace

The kill trace signal disables any output of the ETM block. The ETM can be accessed either via JTAG port and/or by direct software code. Blocking the JTAG port also yields assertion of the kill trace signal. This resulted in blocking of trace port. The intention of this action is to block any attempt to break into the system via software manipulation of the debug modules. The kill trace, when active, prevents trace output even in case where it can be activated via chip pin.

The kill trace feature needs to be activated by burning a dedicated e-fuse. If the fuse is left intact, kill trace is never activated as seen in [Figure 48-13](#).

Figure 48-13. Kill Trace eFUSE

The kill trace is asserted when "kill trace enable" fuse is burned and "ipt_secur_block" signal in SJC is asserted, which happens when at least one of the following is true:

- Mode #2 (Secure JTAG) and no code has been entered
- Mode #2 (Secure JTAG) with burned Bypass and Re-enable fuses
- Mode #2 (Secure JTAG) with incorrect response entered
- Mode #1 (No debug)
- TRST_B signal is active
- POR has not ever been asserted

48.6.4 SJC Disable Fuse

In addition to the different JTAG security modes that are implemented internally in the System JTAG Controller (SJC), there is an option to disable the SJC functionality by eFUSE configuration. This creates additional JTAG mode that is, JTAG Disabled with highest level of JTAG protection. In this mode all JTAG features are disabled.

Specifically, the following debug features are disabled in addition to the features that were already disabled in No Debug JTAG mode:

- Memory BIST
- Boundary scan register (SJC_BSR)
- Non-Secure JTAG control registers (PLL configuration, Deterministic Reset, PLL bypass)
- Non-Secure JTAG status registers (Core status)
- Chip Identification Code (IDCODE)

48.7 Functional Description

This section provides a complete functional description of the block.

48.7.1 Static Core Debug

The SJC JTAG TAP controller is fully compatible with the IEEE 1149.1a-2001 Standard Test Access Port and Boundary Scan Architecture specifications.

The ARM platform has an integrated JTAG interface and a TAP controller to manage its own ICE. Also it can access an embedded trace ETM interface, see ARM core and ETM Technical reference guide for more information.

The SDMA has a TAP controller to manage its own OnCE, see SDMA OnCE specifications for more details.

The OnCE and ICE provide a mean of interacting with the cores and their peripherals non-intrusively so that a user may examine registers, memories to facilitate hardware and software development. Refer to [TAP Selection Block \(TSB\)](#), for more information.

48.7.2 Reset Mechanism

The following figure shows the SJC reset logic

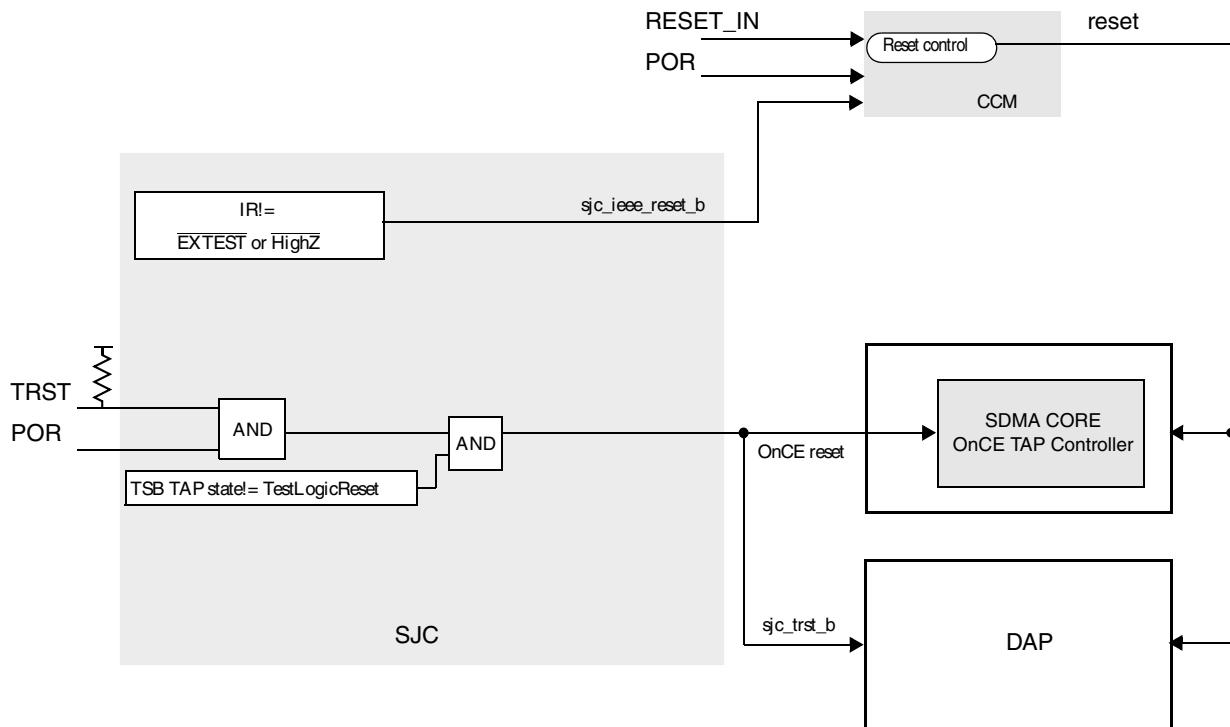

Figure 48-14. SJC Reset Logic

NOTE

- Asserting TRSTB in any scan mode resets the TCR losing the testmode configuration and selects default TAP.
- SJC generates an IEEE reset signal to the CCM when in one of the IEEE modes HIGHZ or EXTEST. This signal generates a system reset to the cores until exit from one of these modes.
- The TSB generates Once/ICE reset (either TRSTB if implemented or other) when its TAP state reaches Test-Logic-Reset (meaning that TAP accessed is also reaching Test-Logic-Reset).

48.8 Initialization/Application Information

The control afforded by the output enable signals using the boundary scan register and the EXTEST instruction requires a compatible circuit-board test environment to avoid device-destructive configurations. The user must avoid situations in which the SJC output drivers are enabled into actively driven networks.

There are two constraints related to the JTAG interface:

- Ensure that the JTAG test logic is kept transparent to the system logic by forcing TAP into the Test-Logic-Reset controller state. During power-up, SJC's internal TRSTB is asserted as IC's POR_B is asserted which forces the TAP controller into this state. After that, if TMS either remains unconnected or is connected to VCC, then the TAP controller cannot leave the Test-Logic-Reset state, regardless of the state of TCK.
- DE_B is an IO pin with pullup and care must be taken of the direction when driving this signal.

48.9 SJC Memory Map/Register Definition

In addition to the standard accessible JTAG registers (per IEEE1149.1 standard) listed in [SoC JTAG Instruction Register \(SJIR\)](#) , the chip contains the following registers accessed using the ExtraDebug mechanism, controlled via "ENABLE_ExtraDebug" IR instruction.

NOTE

SJC registers are only accessible by JTAG interface. They are not memory mapped to processor address space, so the absolute addresses provided by default in the SJC memory map are not valid.

This section assumes the JTAG controller is accessed in standalone mode or daisy chained (defined by TAP Selection Block) using the appropriate TSB configuration.

See "System Debug" chapter for more details about the general purpose register descriptions that are unique to this chip.

SJC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	General Purpose Unsecured Status Register 1 (SJC_GPUSR1)	32	R	0000_0000h	48.9.1/3191

48.9.7 General Purpose Clocks Control Register (SJC_GPCCR)

This register is used to configure clock related modes in SOC, see System Configuration chapter for more information. Those bits are directly connected to JTAG outputs. Bit 0 of GPCCR controls SDMA clocks invocation. When out of reset, the SDMA is in sleep mode with no SDMA clock running. Unlike events, debug requests does not wake SDMA if it is in sleep mode. The debug request is recognized by the SDMA only when it exits sleep mode upon reception of an event. To be able to enter debug mode even if no event is triggered, the SDMA clock on bit needs to be set prior to sending the debug request (clear at reset).

Address: 0h base + 7h offset = 7h

SJC_GPCCR field descriptions

Field	Description
31–2 -	Reserved
1 ACLKOFFDIS	Disable/prevent ARM platform clock/power shutdown
0 SCLKR	SDMA Clock ON Register - This bit forces the clock on of the SDMA

Chapter 49

Secure Non-Volatile Storage (SNVS)

49.1 SNVS overview

The low-power (battery-backed) section incorporates a secure real time counter, a monotonic counter, and a general-purpose register. This portion of the block is powered by a battery that maintains the state of the SNVS_LP registers when the chip is powered off.

Figure 49-1. Example SNVS connectivity

49.1.1 SNVS features

This table summarizes the features:

Table 49-1. SNVS feature summary

Feature	What it does
Non-secure real-time counter (HPRTC)	<ul style="list-style-type: none">• The counter is driven by a dedicated clock which is off when the system power is down• Programmable time alarm interrupt• Periodic interrupt can be generated with different frequencies
Monotonic counter	<ul style="list-style-type: none">• The monotonic counter state is non-volatile• The counter can only increment• The counter is a non-rollover counter• The counter value is invalidated in case of security violation
General-purpose register	<ul style="list-style-type: none">• The general-purpose register state is non-volatile
Register access protection	<ul style="list-style-type: none">• Privileged software access policy• Registers can be programmed only when the system security monitor is in a functional state• Some registers/values can only be programmable once per a boot cycle

49.1.2 Modes of operation

The SNVS operates in either the system power-down or the system power-up mode of operation.

During system power-down, the SNVS_HP is powered down. The SNVS_LP is powered from the backup power supply and is electrically isolated from the rest of the chip. In this mode, the SNVS_LP retains the state of its registers .

During the system power-up, the SNVS_HP and SNVS_LP are both powered up and all SNVS functions are operational.

49.2 SNVS structure

The SNVS block is divided into two major submodules based on power supply: the high power domain (SNVS_HP) and the low power domain (SNVS_LP). They are powered as follows:

- SNVS_LP - dedicated always-powered-on domain
- SNVS_HP - system (chip) power domain

The following figure illustrates the low power and chip power domains of SNVS.

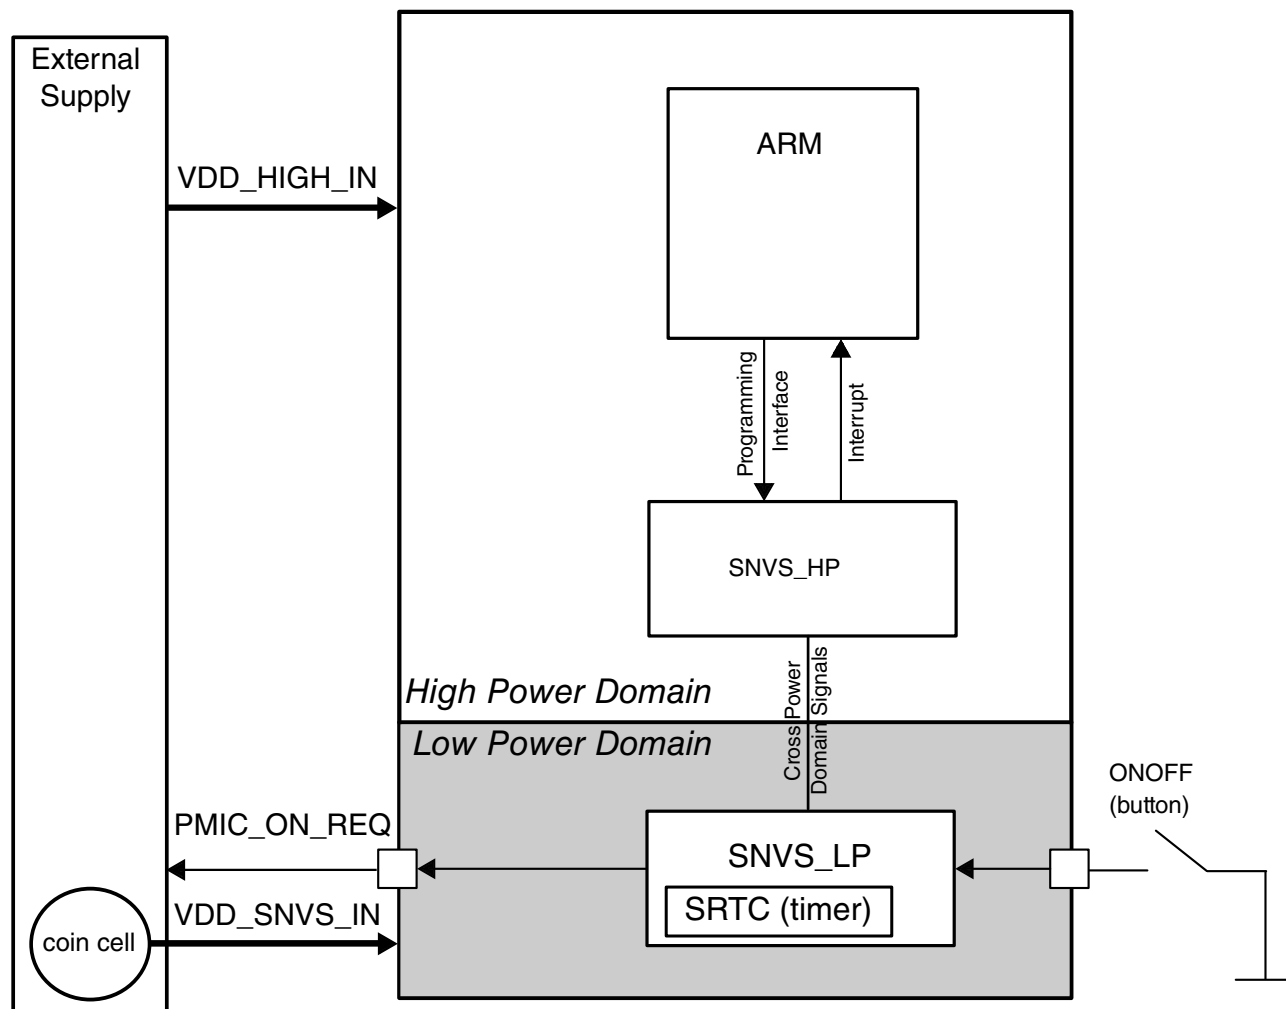

Figure 49-2. SNVS Power Domains

The SNVS_HP section implements all features that enable system communication and provisioning of the SNVS_LP section.

The SNVS_LP section provides hardware that enables secure storage and protection of sensitive data.

49.2.1 SNVS_HP (high-power domain)

The SNVS_HP is partitioned into these functional units:

- IP bus interface
- SNVS_LP interface
- Real-time counter with alarm
- Control and status registers

The SNVS_HP is in the chip's power-supply domain and thus receives the power along with the rest of the chip. The SNVS_HP provides an interface between the SNVS_LP and the rest of the system; there is no way to access the SNVS_LP registers except through the SNVS_HP. For access to the SNVS_LP registers, the SNVS_HP must be powered up. It uses a register access permission policy to determine whether the access to the particular registers is permitted.

49.2.2 Non-secure real-time counter

The SNVS_HP has an autonomous non-secure real-time counter. The counter is not active and is reset when the system is powered down. The HP RTC can be used by any application; it has no privileged software access restrictions. The counter can be synchronized with the SNVS_LP SRTC by writing to a specific bit in the SNVS_HP control register.

49.2.2.1 Calibrating the time counter

The RTC accuracy may suffer from a drift in the clock, which is used to increment the RTC register. To compensate for this drift, a clock calibration mechanism can adjust the RTC value. It is up to the system processor to decide whether the calibration is required or not. If the RTC correction is required, enable the mechanism and set the calibration value in the control register. The calibration value is a 5-bit value including the sign bit, which is implemented in the 2's complement.

If the calibration mechanism is enabled, the calibration value is added or subtracted from the RTC on a periodic basis, once per 32768 cycles of the RTC clock.

This table shows the available correction range:

Table 49-2. Time counter calibration settings

Calibration value setting	Correction in counts per 32768 cycles of the counter clock
01111	+15
:	:
00010	+2
00001	+1
00000	0
11111	-1
11110	-2
:	:
10001	-15
10000	-16

49.2.2.2 Time counter alarm

The SNVS_HP non-secure RTC has its own time-alarm register. Any application can update this register. The SNVS_HP time alarm can generate interrupts to alert the host processor and can wake up the host processor from one of its low-power modes. Note that this alarm can't wake up the entire system if it is powered off because this alarm would also be powered off.

49.2.2.3 Periodic interrupt

The SNVS_HP non-secure RTC incorporates a periodic interrupt. The periodic interrupt is generated when a zero-to-one or one-to-zero transition occurs on the selected bit of the RTC. The periodic interrupt source is chosen from the 16 bits of the HP RTC according to the PI_FREQ field setting in the HP control register. This bit selection also defines the frequency of the periodic interrupt.

This figure shows the SNVS_HP RTC and its interrupts:

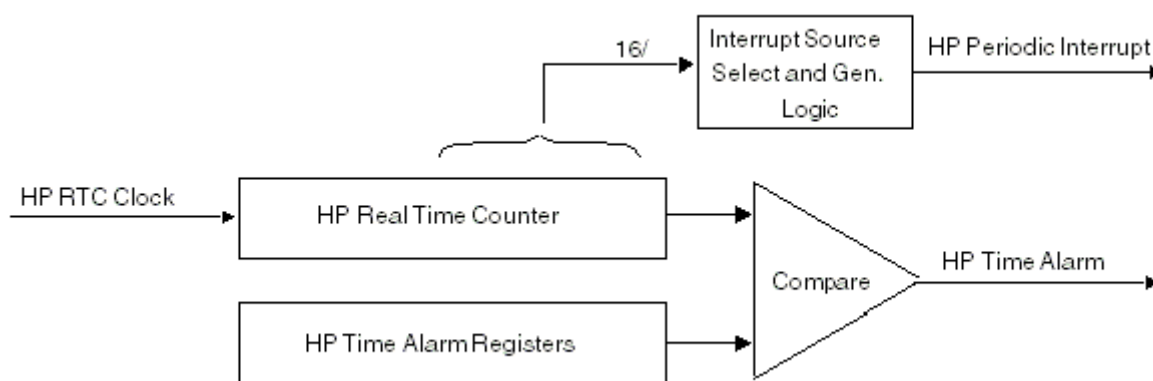

Figure 49-3. SNVS_HP RTC, alarm, and interrupts

49.3 SNVS_LP (low-power domain)

The SNVS_LP has these functional units:

- Non-rollover monotonic counter
- General-purpose register
- Control and status registers

The SNVS_LP is a data storage subsystem. Its purpose is to store and protect system data, regardless of the main system power state.

The SNVS_LP is in the always-powered-up domain, which is a separate power domain with its own power supply.

49.3.1 Behavior during system power down

When the chip power-supply domain loses power, the The SNVS_LP continues to operate normally and ignores all inputs from the SNVS_HP.

49.3.2 Monotonic Counter (MC)

This figure shows the MC and its rollover security violation:

Figure 49-4. SNVS_LP monotonic counter

Some security applications require the Monotonic Counter (MC) that can't be exhausted or returned to any previous value during the product's lifetime. Because the MC can never repeat a number, it can't be reset or cycled back to its starting count. If it reaches its maximum value, it does not rollover. Instead, a monotonic counter rollover indication is generated to the SNVS_LP tamper monitor. This generates an interrupt to the host processor.

The SNVS uses an ERA value derived from the OTP elements as a mechanism to recover from an MC failure (for example, due to a failure of the LP power) where the MC value was compromised or cleared. The ERA value is prepended to the MC to form its most

significant bits. Once any of the ERA value bits are set, the MC can count up from any value, including zero. This guarantees that any future value of the combined monotonic counter is greater than any of its past values.

49.4 SNVS reset and system powerup

This table describes the reset actions for the SNVS.

Table 49-3. Reset summary

Reset	Source	Characteristics	Internally resets
HP hard	ipg_hard_async_reset_b	active-low, asynchronous	All SNVS_HPSNVS_LP registers and flops.
LP Power On Reset (POR)	lp_por_b	active-low, asynchronous	All SNVS_LP registers and flops.
LP software reset	software	active-high, synchronous, one cycle	All SNVS_LP registers and flops. The LP software reset can be asserted if not disabled.

49.4.1 PMIC interface

The on/off logic inside the SNVS_LP allows for connecting directly to a PMIC or other voltage-regulator device. The logic takes the button input signal and then outputs the PMIC "ON" request and the "Power Off" interrupt. The PMIC logic also supports the SNVS_LP tamper logic which allows to wake the system up when a tamper event has happened while in the OFF state. The logic has two different modes of operation (the dumb and smart modes).

Dumb PMIC mode:

The dumb PMIC mode uses the PMIC "ON" request to issue a level signal for the ON and OFF states. The dumb pmic mode has many different configuration options which include debounce, off-to-on time, and maximum timeout).

- **Debounce**—the debounce configuration supports 0 ms, 50 ms, 100 ms, and 500 ms. The debounce is used to generate the set_pwr_off_irq interrupt. While it is in the ON state and the button is pressed longer than the debounce time, the set_pwr_off_irq is generated.

- Off-to-on time—the off-to-on configuration supports 0 ms, 50 ms, 100 ms, and 500 ms. This configuration supports the time it takes to request the power-on after the configured button press time is reached. When the button is pressed longer than the configuration time, the state machine transitions from the OFF to the ON state.
- Max timeout—the maximum timeout configuration supports 5 s, 10 s, 15 s, and disable. This configuration supports the time it takes to request the power down after the button is pressed for the defined time.

The dumb PMIC mode uses a 2-state state machine, as shown in the following figure. The output of the pmic_en_b is generated by the state of the state machine.

Smart PMIC mode:

The smart PMIC mode is meant to connect to another PMIC. The PMIC "ON" request signal issues a pulse instead of a level signal. The only configuration option available for this mode is the Debounce configuration that is used for the "Power Off" interrupt.

49.5 SNVS interrupts and alarms

SNVS provides these interrupt and alarm lines:

- Functional interrupt (active-low)

- Real-time clock period interrupt
- Power off (button) interrupt

This table summarizes all SNVS interrupts and alarm sources.

Table 49-4. Interrupts and alarms summary

Interrupt	Source	Default configuration ¹	Configuration options
SNVS functional interrupt	RTC time alarm	Disable	Enable/Disable
	RTC periodic interrupt	Disable	Enable/Disable
SNVS power off (button) interrupt	BTN input signal	50 ms debounce	Debounce time

1. Default behavior refers to the setting after the LP/HP reset.

49.6 Programming guidelines

This section provides the initialization and application information for the SNVS module.

49.6.1 RTC control bits setting

All SNVS registers are programmed from the register bus. Therefore, any changes are synchronized with the IP clock. Several registers can also change synchronously with the RTC clock after they are programmed. To avoid IP clock and RTC clock synchronization issues, these values can only be programmed when the corresponding function is disabled. This table presents the list of these values with the control bit setting required for programming:

Table 49-5. RTC synchronized values list

Function	Value/register	Control bit setting
HP section		
HP real-time counter	HPRTCMR and HPRTCLR registers	RTC_EN = 0—HPRTCMR/HPRTCLR can be programmed RTC_EN = 1—HPRTCMR/HPRTCLR can't be programmed
HP time alarm	HPTAMR and HPTALR registers	HPTA_EN = 0—HPTAMR/HPTALR can be programmed HPTA_EN = 1—HPTAMR/HPTALR can't be programmed
HP time calibration value	HPCALB_VAL value	HPCALB_EN = 0—HPCALB_VAL can be programmed HPCALB_EN = 1—HPCALB_VAL can't be programmed

Perform these steps to program the synchronized values:

1. Check the enable bit value. If it is set, clear it.

2. Verify that the enable bit is cleared.

There are two reasons to verify the enable bit's setting:

- The enable bit clearing does not happen immediately. It takes three IPclock cycles and two RTC clock cycles to change the enable bit's value.
- If the enable bit is locked for programming, it can't be cleared.

3. Program the desired value.

4. Set the enable bit. It takes three IP clock cycles and two RTC clock cycles for the bit to set.

NOTE

Incrementing the value programmed into the RTC registers by two compensates for the two RTC clock cycle delays that are required to enable the counter.

49.6.2 RTC value read

There are two scenarios when the software can read the corrupted values from the RTC (HPRTCMR and HPRTCLR) registers:

- The RTC counters are incremented by the slow 32-kHz clock, which is asynchronous to the system clock. The counter value is synchronized to the system clock before the software reads that. The synchronization register can capture the counter value in the middle of the counter update. In this case, it is not guaranteed that all bits are properly sampled by the synchronization register; the value read by the software can be wrong.
- The RTC value is longer than the single bus read transaction of 32 bits. Therefore, the software reads two registers with each holding a portion of the counter value. After reading one of these registers but before reading the second register, both registers can update their values. In this case, the value combined by the software is incorrect.

To avoid these issues, it is strongly recommended that the software performs two consecutive reads of the RTC value:

- If the two consecutive reads are similar, the value is correct.
- If the two consecutive reads are different, perform two more reads.

The worst-case scenario can require three sessions of two consecutive reads.

49.6.3 General initialization guidelines

Perform these steps to properly initialize the module:

1. Enable the interrupts in the SNVScntrl and configuration registers.
2. Program the SNVS general functions/configurations.
3. User-specific: Set the lock bits.

49.7 SNVS memory map/register definition

This section contains detailed register descriptions for the SNVS registers. Each description includes a standard register diagram and a register table. The register table provides detailed descriptions of the register bit and field functions in the bit order.

The SNVS registers consist of two types:

- Privileged read/write accessible
- Non-privileged read/write accessible

The privileged read/write accessible registers can only be accessed for read/write by the privileged software. Unauthorized write accesses are ignored, and unauthorized read accesses return zero. The non-privileged software can access privileged access registers when the non-privileged software access enable bit is set in the SNVS_HPcommand register.

- Non-secure
- Trusted
- Secure

The non-privileged read/write accessible registers are read/write accessible by any software.

The following table shows the SNVS memory map. The LP register values are set only on the LP POR and are unaffected by the system (HP) POR. The HP registers are set only on the system POR and are unaffected by the LP POR.

SNVS memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
20B_0000	SNVS_HP Lock register (SNVS_HPLR)	32	R/W	0000_0000h	49.7.1/3213
20B_0004	SNVS_HP Command register (SNVS_HPCOMR)	32	R/W	0000_0000h	49.7.2/3215

Table continues on the next page...

SNVS memory map (continued)

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
20B_0008	SNVS_HP Control register (SNVS_HPCR)	32	R/W	0000_0000h	49.7.3/3217
20B_0014	SNVS_HP Status register (SNVS_HPSR)	32	R/W	8000_0000h	49.7.4/3220
20B_0024	SNVS_HP Real-Time Counter MSB Register (SNVS_HPRTC MR)	32	R/W	0000_0000h	49.7.5/3222

W		HPCALB_VAL								PI_FREQ							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

SNVS_HPCR field descriptions

Field	Description
31–28 -	This field is reserved.
27 BTN_MASK	Button interrupt mask. This bit is used to mask the ipi_snvs_btn_int_b (button) interrupt request. 0—interrupt is disabled. 1—interrupt is enabled.
26–24 BTN_CONFIG	Button configuration. This field is used to configure which feature of the button (BTN) input signal constitutes "active".

Table continues on the next page...

SNVS_HPCR field descriptions (continued)

Field	Description
	<p>000—button signal is active-low.</p> <p>001—button signal is active-high.</p> <p>010—button signal is active on the rising edge.</p> <p>011—button signal is active on the falling edge.</p> <p>100—button signal is active on any edge.</p> <p>All other patterns are reserved.</p>
23–17 -	This field is reserved.
16 -	Security-related field
15 -	This field is reserved.
14–10 HPCALB_VAL	<p>HP Calibration Value</p> <p>Defines the signed calibration value for the HP real-time counter. This field can be programmed only when the RTC calibration is disabled (HPCALB_EN is not set). This is a 5-bit 2's complement value, hence the allowable calibration values are in the range from -16 to +15 counts per 32768 ticks of the counter.</p> <p>00000 +0 counts per each 32768 ticks of the counter</p> <p>00001 +1 counts per each 32768 ticks of the counter</p> <p>00010 +2 counts per each 32768 ticks of the counter</p> <p>01111 +15 counts per each 32768 ticks of the counter</p> <p>10000 -16 counts per each 32768 ticks of the counter</p> <p>10001 -15 counts per each 32768 ticks of the counter</p> <p>11110 -2 counts per each 32768 ticks of the counter</p> <p>11111 -1 counts per each 32768 ticks of the counter</p>
9 -	This field is reserved.
8 HPCALB_EN	<p>HP Real-Time Counter Calibration Enabled</p> <p>Indicates that the time-calibration mechanism is enabled.</p> <p>0 HP timer calibration is disabled.</p> <p>1 HP timer calibration is enabled.</p>
7–4 PI_FREQ	<p>Periodic Interrupt Frequency</p> <p>Defines the frequency of the periodic interrupt. The interrupt is generated when a zero-to-one or one-to-zero transition occurs on the selected bit of the HP real-time counter, and the real-time counter and the periodic interrupt are both enabled (RTC_EN and PI_EN are set). It is recommended to program this field when the periodic interrupt is disabled (PI_EN is not set). The possible frequencies are:</p> <p>0000 - Bit 0 of the RTC is selected as the source of the periodic interrupt.</p> <p>0001 - Bit 1 of the RTC is selected as the source of the periodic interrupt.</p> <p>0010 - Bit 2 of the RTC is selected as the source of the periodic interrupt.</p> <p>0011 - Bit 3 of the RTC is selected as the source of the periodic interrupt.</p> <p>0100 - Bit 4 of the RTC is selected as the source of the periodic interrupt.</p> <p>0101 - Bit 5 of the RTC is selected as the source of the periodic interrupt.</p> <p>0110 - Bit 6 of the RTC is selected as the source of the periodic interrupt.</p> <p>0111 - Bit 7 of the RTC is selected as the source of the periodic interrupt.</p>

Table continues on the next page...

SNVS_HPCR field descriptions (continued)

Field	Description
	1000 - Bit 8 of the RTC is selected as the source of the periodic interrupt. 1001 - Bit 9 of the RTC is selected as the source of the periodic interrupt. 1010 - Bit 10 of the RTC is selected as the source of the periodic interrupt. 1011 - Bit 11 of the RTC is selected as the source of the periodic interrupt. 1100 - Bit 12 of the RTC is selected as the source of the periodic interrupt. 1101 - Bit 13 of the RTC is selected as the source of the periodic interrupt. 1110 - Bit 14 of the RTC is selected as the source of the periodic interrupt. 1111 - Bit 15 of the RTC is selected as the source of the periodic interrupt.
3 PI_EN	HP Periodic Interrupt Enable The periodic interrupt can be generated only if the HP real-time counter is enabled. 0 HP periodic interrupt is disabled. 1 HP periodic interrupt is enabled.
2 -	This field is reserved.
1 HPTA_EN	HP Time Alarm Enable When set, the time alarm interrupt is generated if the value in the HP time alarm registers is equal to the value of the HP real-time counter. 0 HP time alarm interrupt is disabled. 1 HP time alarm interrupt is enabled.
0 RTC_EN	HP Real-Time Counter Enable 0 RTC is disabled. 1 RTC is enabled.

49.7.4 SNVS_HP Status register (SNVS_HPSR)

The SNVS_HP status register reflects the internal state of the SNVS.

Address: 20B_0000h base + 14h offset = 20B_0014h

4–2 -	This field is reserved.
1 -	Security-related field
0 -	Security-related field

49.7.5 SNVS_HP Real-Time Counter MSB Register (SNVS_HPRTCMR)

The SNVS_HP real-time counter MSB register contains the most significant bits of the HP real-time counter.

Address: 20B_0000h base + 24h offset = 20B_0024h

SNVS_HPRTCMR field descriptions

Field	Description
RTC	HP Real-Time Counter Most significant 32 bits. This register can be programmed only when the RTC is not active (the RTC_EN bit is not set).

49.7.6 SNVS_HP Real-Time Counter LSB Register (SNVS_HPRTCLR)

The SNVS_HP real-time counter LSB register contains the 32 least significant bits of the HP real-time counter.

Address: 20B_0000h base + 28h offset = 20B_0028h

SNVS_HPRTCLR field descriptions

Field	Description
RTC	HP Real-Time Counter Least significant 32 bits. This register can be programmed only when the RTC is not active (the RTC_EN bit is not set).

49.7.7 SNVS_HP Time Alarm MSB Register (SNVS_HPTAMR)

The SNVS_HP time alarm MSB register contains the most significant bits of the SNVS_HP time alarm value.

Address: 20B_0000h base + 2Ch offset = 20B_002Ch

SNVS_HPTAMR field descriptions

Field	Description
31–15 -	This field is reserved.
HPTA	HP Time Alarm Most significant 15 bits. This register can be programmed only when the HP time alarm is disabled (the HPTA_EN bit is not set).

49.7.8 SNVS_HP Time Alarm LSB Register (SNVS_HPTALR)

The SNVS_HP time alarm LSB register contains the 32 least significant bits of the SNVS_HP time alarm value.

Address: 20B_0000h base + 30h offset = 20B_0030h

SNVS_HPTALR field descriptions

Field	Description
HPTA	HP Time Alarm The least significant bits. This register can be programmed only when the HP time alarm is disabled (the HPTA_EN bit is not set).

49.7.9 SNVS_LP Lock Register (SNVS_LPLR)

The SNVS_LP lock register contains the lock bits for the SNVS_LP registers.

Address: 20B_0000h base + 34h offset = 20B_0034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SNVS_LPCR field descriptions

Field	Description
31–25 -	This field is reserved.
24 -	This field is reserved.
23 PK_OVERRIDE	PMIC On Request Override. The value written to the PK_OVERRIDE is asserted on the output signal snvs_lp_pk_override. This signal is used to override the IOMUX control for the PMIC I/O pad.
22 PK_EN	PMIC On Request Enable. The value written to the PK_EN is asserted on the output signal snvs_lp_pk_en. This signal is used to turn off the pullup/pulldown circuitry in the PMIC I/O pad.
21–20 ON_TIME	The ON_TIME field is used to configure the period of time after the BTN is asserted before the pmic_en_b is asserted to turn on the SoC power. 00: 500 ms off->on transition time 01: 50 ms off->on transition time 10: 100 ms off->on transition time

Table continues on the next page...

SNVS_LPCR field descriptions (continued)

Field	Description
	11: 0 ms off->on transition time
19–18 DEBOUNCE	This field configures the amount of debounce time for the BTN input signal. 00: 50 ms debounce 01: 100 ms debounce 10: 500 ms debounce 11: 0 ms debounce
17–16 BTN_PRESS_ TIME	Button press timeout values for the PMIC logic. 00 : 5 s 01 : 10 s 10 : 15 s 11 : long press is disabled (pmic_en_b is not asserted, regardless of how long the BTN is asserted)
15 -	This field is reserved.
14–10 -	Security-related field
9 -	This field is reserved.
8 -	Security-related field
7 PWR_GLITCH_ EN	By default, the detection of a power glitch does not cause the pmic_en_b signal to be asserted. Setting the power glitch enable bit to 1 enables the power-glitch event for the PMIC. 0—disabled 1—enabled
6 TOP	Turn off System Power Asserting this bit causes a signal to be sent to the power management IC to turn the system power off. This bit clears once the power is off. This bit is only valid when the dumb PMIC is enabled. 0 Leave the system power on. 1 Turn the system power off.
5 DP_EN	Dumb PMIC Enabled When set, the software can control the system power. When cleared, the system requires the smart PMIC to automatically turn the power off. 0 Smart PMIC is enabled. 1 Dumb PMIC is enabled.
4 -	Security-related field
3 -	Security-related field
2 MC_ENV	Monotonic Counter Enable and Valid When set, the MC can be incremented (by a write transaction to the LPSMCMR or LPSMCLR). This bit can't be changed once the MC_SL or MC_HL bits are set.

Table continues on the next page...

49.7.12 SNVS_LP Secure Monotonic Counter MSB Register (SNVS_LPSMCMR)

The SNVS_LP secure monotonic counter MSB register contains the monotonic counter era bits and the most-significant 16 bits of the monotonic counter. The monotonic counter is incremented by one if there is a write command to the LPSMCMR register or the LPSMCLR register.

Address: 20B_0000h base + 5Ch offset = 20B_005Ch

SNVS_LPSMCMR field descriptions

Field	Description
31–16 MC_ERA_BITS	Monotonic Counter Era Bits These bits are the inputs to the module and are typically connected to the fuses.
MON_COUNTER	Monotonic Counter Most-Significant 16 Bits The MC is incremented by one when: <ul style="list-style-type: none"> • A write transaction to the LPSMCMR register or the LPSMCLR register is detected. • The MC_ENV bit is set. • The MC_SL and MC_HL bits are not set.

49.7.13 SNVS_LP Secure Monotonic Counter LSB Register (SNVS_LPSMCLR)

The SNVS_LP secure monotonic counter LSB register contains the 32 least-significant bits of the monotonic counter. The MC is incremented by one if there is a write command to the LPSMCMR register or the LPSMCLR register.

Address: 20B_0000h base + 60h offset = 20B_0060h

SNVS_LPSMCLR field descriptions

Field	Description
MON_COUNTER	Monotonic Counter bits The MC is incremented by one when: <ul style="list-style-type: none"> • A write transaction to the LPSMCMR register or the LPSMCLR register is detected. • The MC_ENV bit is set. • The MC_SL and MC_HL bits are not set.

49.7.14 SNVS_LP General-Purpose Register (SNVS_LPGPR)

The SNVS_LP general-purpose register is a 32-bit read/write register located in the low-power domain. Because the LPGPR is located in the battery-backed power domain, the LPGPR can be used by any application for retaining data during the SoC power-down mode. The LPGPR is automatically zeroized when a tamper event occurs, unless the GPR zeroization is disabled via the GPR_Z_DIS bit in the LP control register.

Address: 20B_0000h base + 68h offset = 20B_0068h

SNVS_LPGPR field descriptions

Field	Description
GPR	General-Purpose Register When the GPR_SL or GPR_HL bit is set, the register can't be programmed.

49.7.15 SNVS_HP Version ID Register 1 (SNVS_HPVIDR1)

The SNVS_HP Version ID Register 1 is a read-only register that contains the current version of the SNVS. The version consists of a module ID, a major version number, and a minor version number.

Address: 20B_0000h base + BF8h offset = 20B_0BF8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Chapter 50

Shared Peripheral Bus Arbiter (SPBA)

50.1 Overview

The Shared Peripheral Bus Arbiter (SPBA) is a three-to-one IP Bus interface arbiter. Three masters arbitrate for shared peripheral access through the SPBA.

The SPBA has three primary functions:

- The IP Bus Line switches a master to one peripheral
- The Masters arbiter arbitrates between the three masters to solve concurrent access or restricted access to peripherals
- The Control Registers and Ownership Control includes a set of registers which are reachable through software and permit the access scheme to be defined for each peripheral (Resource Ownership and Access Control). It generates signals for the external steering logic of interrupts and DMA signals.

The figure below shows the SPBA block diagram

Figure 50-1. SPBA Block Diagram

50.1.1 Features

The SPBA includes the following features:

- Three IP Bus masters arbitration: Master A, B and C
- Support for DMA masters
- 32-bit data
- Supports up to 31 shared peripherals, each consuming 16 kilobytes of address space
- SPBA can be considered the 32nd peripheral, used for resource ownership and access control of the 31 peripherals
- Provides 31 sets of out of band steering control (OBSC) signals to the off-block steering logic
- Operating frequency up to 67 MHz
- Clocks: ipg_clk, ipg_clk_s

50.1.2 Modes of operation

SPBA behavior is transparent when accessing a peripheral, though it has these distinct modes of operation.

Reset/Abort

The SPBA has a hardware reset which initializes all registers, arbitration and peripherals rights registers (PRRs).

An abort signal input is provided allowing each master to abort its current access and release ownership (in case of master reset sequence).

Functional

Once a master request is granted, its IP Bus signals are steered to the requested peripheral.

Standby

No clock needed. The SPBA needs clocks only during access to the PRRs, arbitration, and abort phases. It generates two clock enable signals indicating when the clocks must be provided.

Configuration

During this phase, a master accesses the SPBA PRRs. The SPBA memory-mapped registers are seen as a shared peripheral.

50.2 Clocks

The table found here describes the clock sources for SPBA.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 50-1. SPBA Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

50.3 Functional description

50.3.1 Masters arbitration

The arbitration mechanism determines which port will control the master port, based on a simple round-robin arbitration scheme.

There are several use cases to consider.

- Only one master request per access. The master is switched to the shared peripheral bus, without arbitration. [Figure 50-2](#) shows the MB request on the global module enable signal, served without wait state.
- If two masters simultaneously access SPBA, the last granted master is held off using the <master>_ips_xfr_wait output signal (default value is high). When the master is granted sips_xfr_wait, shared IP Bus peripheral is connected to <master>_ips_xfr_wait outputs.
- If three masters simultaneously access SPBA, then the last two granted masters are held off using <master>_ips_xfr_wait. [Figure 50-3](#) shows a case in which the last two accesses granted are MA and MB. The requests are used even if they are in the same cycle.
- If after reset, at the first multiple access, no master has been granted, the priority is static: Master A (MA), Master B (MB) and last Master C (MC) port.
- No master request. No master switch to shared peripherals.

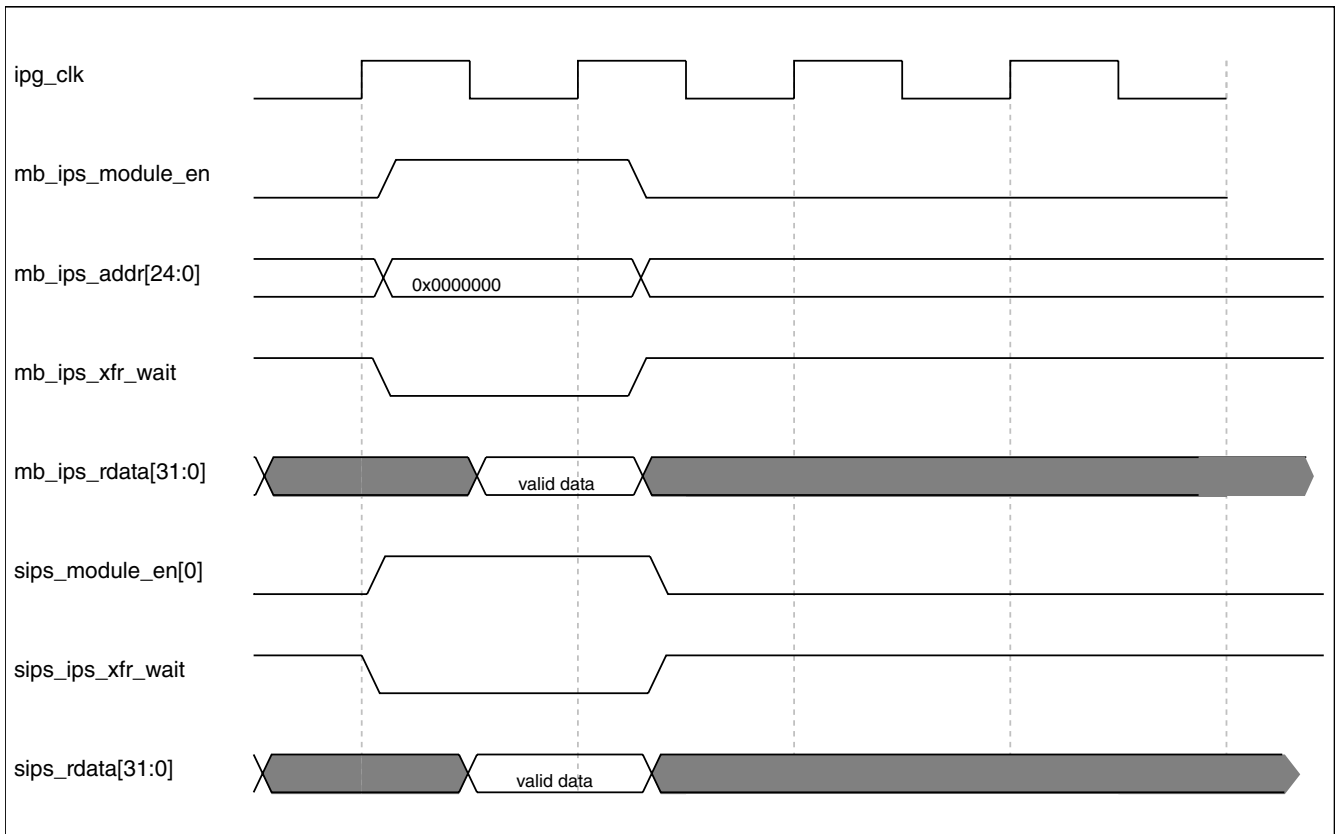

Figure 50-2. Example of one master request, no SPBA arbitration

The following figure assumes MA and MB have been the last two masters granted in the previous transfers (MA then MB).

Functional description

Figure 50-3. Example of three master requests: Masters already granted are "waited";

50.4 Resource ownership control

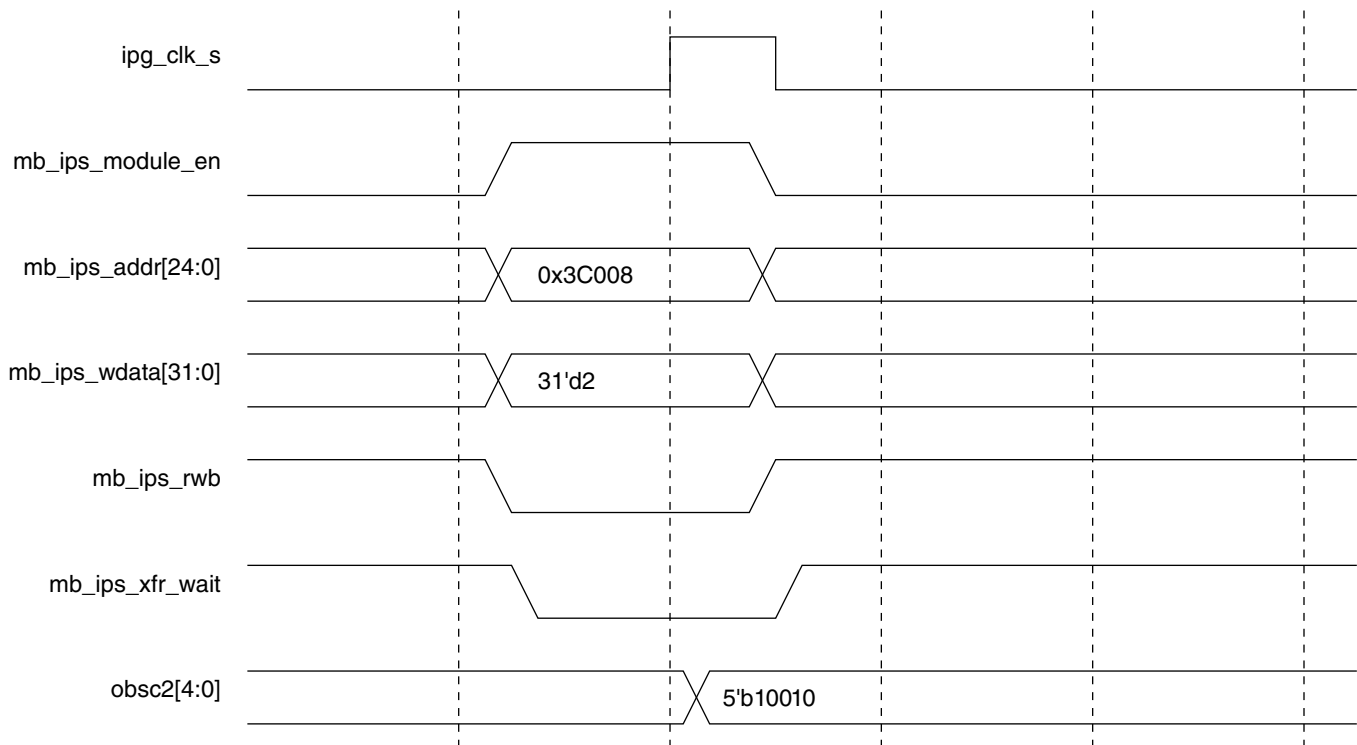

The resource ownership control regulates access to the shared peripherals and determines the steering of out-of-band signals.

50.4.1 Access control

50.4.1.1 Peripheral access

The peripheral access (resource access) of the requesting master is given by the corresponding RAR bit of the Peripheral Right Register. It determines if the master has access privilege to the resource.

Any attempt at access made by a requesting master whose access privilege bit is not set (in the PRR) is terminated with a bus error (<master>_ips_xfr_err is asserted by SPBA logic). The master that owns the resource can lock the peripheral for itself and/or grant other masters access to the peripheral by setting the appropriate bit(s) in the RAR field.

Master B is taking ownership of peripheral 2 by writing 3'b010 in the SPBA peripheral 2 right register (rarfield)
 This ownership can be checked on obsc2 output as roi2[1:0] = 2'b10 and rar2[2:0] = 3'b010
 (obsc[4:0] = {roi2[1], roi2[0], rar2[2], rar2[1], rar2[0]})

Figure 50-4. Example of one master B gaining ownership of peripheral 2

50.4.1.2 Peripheral Right Register access

The ROI bits of the Peripheral Right Register (PRR) determine which master is allowed to make write access to PRR. The identification of the requesting master is compared to the ROI bits of the PRR to determine if the master has ownership of the corresponding register.

Any attempted write access to a PRR already owned by another master will be ignored.

50.4.2 Owner election

When the peripheral is not owned by any master (ROI="00", after coming out of reset for instance), the first master to perform successfully a write to the RAR bits of the PRR is granted ownership of the peripheral and its associated PRR.

After writing to the PRR (RAR bit(s)), the master must read it back to make sure that it was granted ownership. If the RMO field is 2'b11, then the ownership claim is successful. If RMO is 2'b10, another master claimed ownership before this master was able to complete its write. This resolves the case in which two or more masters attempt to write the PRR at the same time; only the first master will be granted ownership. However all masters must read the PRR to determine if this case occurred, and if so, whether they were the first master which was granted ownership.

NOTE

A master that has been granted ownership of the PRR does not automatically have the right access to the peripheral; it must still set its own RAR bits in the PRR to access the peripheral.

50.4.3 Ending ownership

Ownership may be voluntarily ended by the owning master, or automatically upon assertion of a master-specific dead_owner signal.

The former is appropriate for software-controlled yielding of ownership. The latter is appropriate for automatic yielding of ownership when the owner has gone into reset.

When a master is reset, it clears the ROI bits of the PRRs owned by the corresponding master. When the owner is dead (in reset), all peripherals previously owned by that master must be changed to the un-owned state.

NOTE

It is the programmer's responsibility to make sure the peripherals are placed in an appropriate state before ending ownership.

50.4.3.1 Software Controlled Ownership Ending

The ROI bits will be automatically cleared when the master that owns the PRR access right clears (write) the RAR bits ([Table 2](#)).

It will then end the ownership of the PRR.

50.4.4 The Un-owned State

During the time when the peripheral is un-owned (i.e the ROI field contains all 0's), all masters have full access to it (RAR bits can then be modified by a master if ROI[1:0] = 2'b0).

In such cases it is necessary for software to ensure any necessary coherency in the resource, there is no hardware protection.

50.5 SPBA Memory Map/Register Definition

The SPBA control registers (Peripheral Right Registers) are mapped as a virtual shared peripheral.

SPBA can support up to 31 shared peripherals. Each of them has its own Peripheral Right Register (PRR) accessible within the SPBA memory-mapped registers, and consists of the Requesting Master Owner, the Resource Owner ID and the Resource Access Right fields.

SPBA memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

0 RARA	<p>Resource Access Right. Control and Status bit for master A.</p> <p>This field indicates whether master A can access the peripheral. From 0 up to 3 masters can have permission to access a resource (all the master can be granted on a peripheral, but only one access at a time will be granted by SPBA).</p> <p>0 PROHIBITED — Access to peripheral is not allowed. 1 ALLOWED — Access to peripheral is granted.</p>

Chapter 51

Sony/Philips Digital Interface (SPDIF)

51.1 Overview

The Sony/Philips Digital Interface (SPDIF) audio block is a stereo transceiver that allows the processor to receive and transmit digital audio.

The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency.

A recovered clock is provided to drive both internal components in the system, such as SAI ports, and external components, such as A/Ds or D/As, with clocking control provided via related registers.

As the SPDIF internal data width is 24-bit, the eight most-significant bits of all registers return zeros.

The figure below shows a block diagram of the SPDIF transceiver data paths (receiver and transmitter) and its interface.

Figure 51-1. SPDIF Transceiver Data Interface Block Diagram

51.2 External Signals

The following table describes the external signals of SPDIF:

Table 51-1. SPDIF External Signals

Signal	Description	Pad	Mode	Direction
SPDIF_EXT_CLK	External clock signal	LCD_DATA07	ALT4	I
		NAND_DQS	ALT1	
SPDIF_IN	Input line	GPIO1_IO09	ALT2	I
		LCD_DATA08	ALT4	
		SD1_CLK	ALT1	
		UART1_RX_DATA	ALT6	
SPDIF_LOCK	Lock signal	LCD_DATA06	ALT4	O
SPDIF_OUT	Output line signal	GPIO1_IO08	ALT2	O
		JTAG_MOD	ALT4	
		LCD_DATA05	ALT1	
		SD1_CMD	ALT6	
		UART1_TX_DATA	ALT6	
SPDIF_SR_CLK	SR clock signal	LCD_DATA04	ALT4	O

51.3 Clocks

The table found here describes the clock sources for SPDIF.

Please see clock control block for clock setting, configuration and gating information.

Table 51-2. SPDIF Clocks

Clock name	Clock Root	Description
gclkw_t0	ipg_clk_root	Global clock
ipg_clk_s	ipg_clk_root	Peripheral access clock
tx_clk	spdif0_clk_root	Module Tx clock

51.4 Functional Description

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter.

Functional Description

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in the SPDIF Rx left and right FIFOs. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates a SPDIF output bitstream in the biphas mark format (IEC60958), which consists of audio data, channel status and user bits.

In the SPDIF transmitter, the IEC60958 biphas bit stream is generated on both edges of the SPDIF Transmit clock. The SPDIF Transmit clock is generated by the SPDIF internal clock generate block and the sources are from outside of the SPDIF block. For the SPDIF receiver, it can recover the SPDIF Rx clock. [Figure 1](#) shows the clock structure of the SPDIF transceiver.

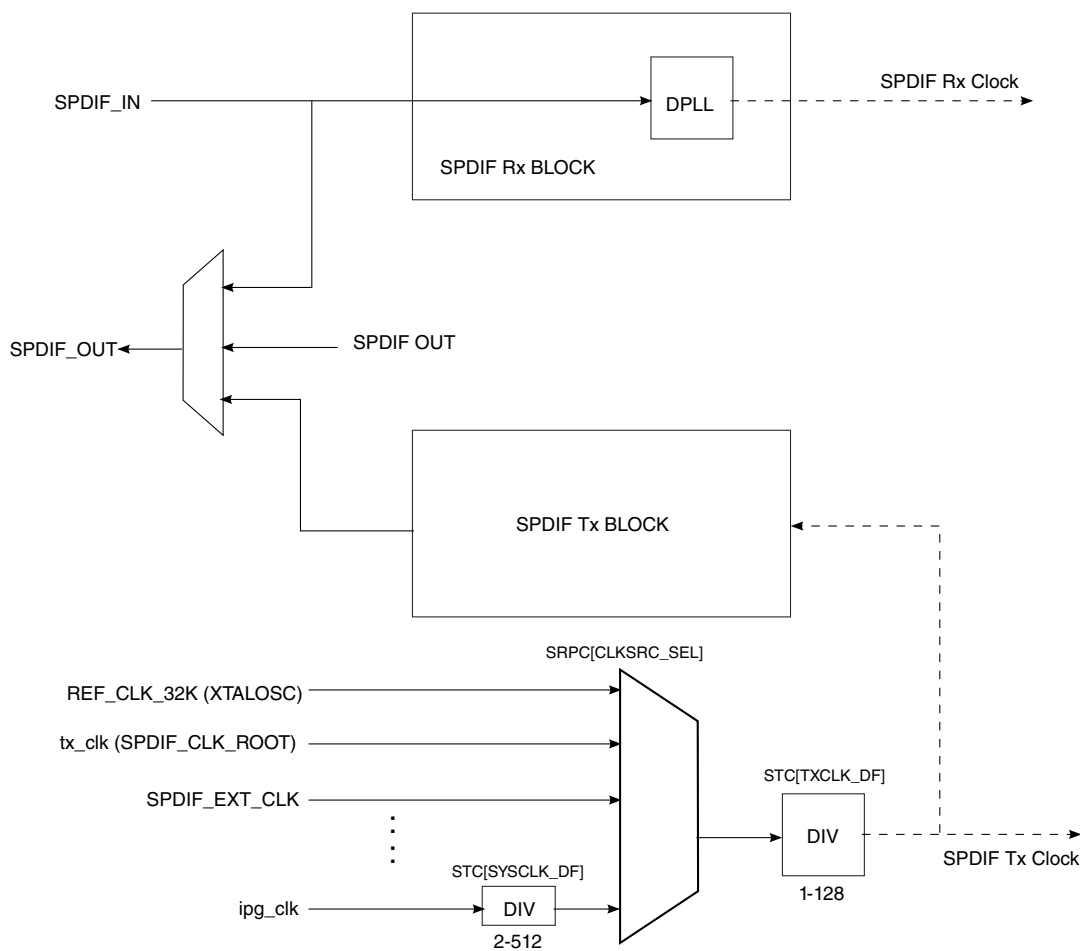

Figure 51-2. SPDIF Transceiver Clock Diagram

51.4.1 SPDIF Receiver

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in Rx left and right FIFOs.

The Tx left and right FIFOs are 16-deep and 24-bit-wide (equal to the audio data width). The Channel Status and User Bits are also extracted from each frame and placed in corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

The SPDIF receiver handles the main data audio stream and recovers the bit clock from the SPDIF input signal. The sample rate can be determined from the frequency measuring block. Additionally, the receiver supports the SPDIF C and U channels. The SPDIF C and U channel data is interfaced directly to memory-mapped registers.

All the data registers are controlled by the Interrupt Control Block and transferred to the memory-mapped IP bus.

The following functions are performed by the SPDIF receiver:

- Audio Data Reception see [Audio Data Reception](#)
- Channel Status bits Reception see [Channel Status Reception](#)
- U Channel bits Reception see [User Bit Reception](#)
- Validity Flag Reception see [Validity Flag Reception](#)
- SPDIF Receiver Exception support see [SPDIF Receiver](#)
- SPDIF Lock Detection

51.4.1.1 Audio Data Reception

The SPDIF Receiver block extracts the audio data from the IEC60958 stream, and outputs this via Rx left and right FIFOs to the memory-mapped registers SPDIFRxLeft and SPDIFRxRight.

Data from the SPDIF receiver is buffered in receive FIFO, and can be read by the processor from the memory-mapped registers.

- **SPDIF receiver data registers - Behavior on overrun, underrun**

The SPDIF Data Receive registers (SPDIFRxLeft and SPDIFRxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect

only one part (left or right) of any FIFOs. To prevent this from happening, hardware has been added to the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If a SPDIF Data Rx FIFO overrun occurs on e.g. the right half of the FIFO, the sample that caused the overrun is not written to the right half (due to overrun). Special hardware will make sure the next sample is not written to the left half of the FIFO. If the overrun occurs on the left half of the FIFO, the next sample is not written to the right half of the FIFO.

- **SPDIF receiver data registers - Automatic resynchronization of FIFOs**

An automatic FIFO resynchronization feature is available. It can be enabled and disabled separately for every FIFO. If it is enabled, the hardware will check to see if the left and right FIFOs are in sync. If that is not the case, it will set the filling pointer of the right FIFO to be equal to the filling pointer of the left FIFO.

Figure 51-3. FIFO Auto-resync Controller State Machine

The operation is explained from the state diagram shown above. Every FIFO auto-resync controller has a state machine with 3 states: Off, StandBy and On. In the On state, the filling of the left FIFO is compared with the filling of right, and if they are not equal, right is made equal to left, and an interrupt is generated.

The controller will stay in Off state when the feature is disabled. When not disabled, the state machine will go to Off state on any processor read or write to the FIFO. It will go from On or Off to Standby on any left sample read from SPDIF Tx FIFOs, or on any left sample write to SPDIF Rx FIFOs. The controller will go from Standby to On on any right sample read from SPDIF Tx FIFO, or on any right sample write to SPDIF Rx FIFO. There is a control bit in the SPDIFConfig register to enable/disable the feature for the SPDIF Rx FIFO and SPDIF Tx FIFO.

51.4.1.1.1 Application Note

The automatic FIFO resynchronization can be switched on, and will avoid all mismatches between left and right FIFOs, if the software obeys the following rules: 1. When the left data is read or written to the left FIFO, in the same place of the program, data must be read or written to the right FIFO. Maximum time difference between left and right is 1/2 sample clock. (E.g. if sample frequency is 44 KHz, approximately 10 micro-seconds. For 88 KHz, approximately 5 micro-seconds.) 2. Write/read data to FIFOs at least 2 samples at the time. If there is a mismatch Left-Right, the resync logic may go on only 1 sample clock after last data is read/written to the FIFO. Also acceptable is polling the FIFO, if at least part of the time 2 samples will be read/written to it.

- **SPDIF receiver - Additional features**

There are three exceptions associated with the SPDIF Receivers FIFOs

- full
- under/overflow
- resync

When the "full" condition is set for processor data input registers, the processor should read data from the FIFO, before overflow occurs. When "full" is set, and the FIFO contains e.g. 6 samples, it is acceptable for the software to read first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 6 samples from the RIGHT address, followed by 6 samples from the LEFT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. There is no order specified.

The implementation for SPDIF Rx is a double FIFO, one for left and one for right. "full" is set when both FIFOs are full. "underrun, overflow" are set when one of the FIFOs do underrun or do overflow. The resync interrupt means hardware took special action to resynchronize left and right FIFOs.

The FIFO level at which the "full" interrupt is generated, is programmable via the Full Select field in the SPDIFConfigReg register.

Rx FIFO on and Rx FIFO reset.

Two additional control fields of the SPDIF Rx FIFO are the on/off select and FIFO reset fields.

If on/off select is set to off, all-zero will be read from the FIFO, irrespective of the data received over the SPDIF interface.

If FIFO reset is set, the FIFO is blocked at "1 sample in FIFO". In this, the full interrupt will be on if FullSelect is set to "00". If FullSelect is set to any other value, interrupt will be off. The other interrupts are always off.

51.4.1.2 Channel Status Reception

A total of 48 channel status bits are received in two registers. No interpretation is performed by the SPDIF receiver block.

Channel Status Bits are ordered first bit left. CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFRxCCchannel_h. CS-channel bit "23" is considered the LSB bit 0 in the register. C-channel bit 24 to 47 is seen as [23:0] bits of register SPDIFRxCCchannel_l.

51.4.1.2.1 Channel Status Interrupt

When the value of a new SPDIF "CS" channel status frame is loaded in the register, an interrupt is generated. The interrupt is cleared when the processor writes the corresponding bit in the InterruptStat register.

51.4.1.3 User Bit Reception

There are two modes for U Channel reception, CD and non-CD. As is decided by USyncMode (bit 1 of CDText_Control register).

- **Behavior of U Channel receive interface on incoming CD U Channel Sub-code in SPDIF receiver.**

This mode is selected if UsyncMode, bit 1 in register CD Text control is set "1".

The CD sub-code stream embedded into the SPDIF U channel consists of a sequence of packets. Every packet is made up 98 "symbols". The first two symbols of every packet are "sync symbols", the other 96 symbols are "data symbols".

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

Data symbols are coming in MSB first. The MSB is the leading one.

When a "long pause" is seen between 2 subsequent "data symbols", the SPDIF receiver will assume the reception of one or more "sync symbols". Table below gives details.

Table 51-3. Sync Control Bits

Number of U Channel zero bits	Corresponding number of sync symbols
0-1	Unpredictable, not allowed
2-10	0
11-22	1
23-34	2
35-46	3
>45	Unpredictable, not allowed

The recognition of the number of sync symbols derives from the fact that the U channel transmitter in the CD channel decoder will transmit one symbol on average every 12 SPDIF channel bits. On this average rate, there is a maximum tolerance of 5%.

The SPDIF receiver is tolerant of symbol errors. Due to the physical nature of the transmission of the data over the CD disc, not more than 1 out of any 5 consecutive user channel symbols may be in error. The error may cause a change in data value, which is not detected by this interface, or it may cause a data symbol to be seen as a sync symbol, or a sync symbol to be seen as a data symbol. However, not more than 1 out of any 5 consecutive user channel symbols should be affected in this way.

The SPDIF U channel circuitry recognizes the 98-symbol packet structure, and sends the 96 symbol payload to the processor application. The 96 symbol payload is transmitted to the processor via 2 registers:

- The SPDIFRxUChannel register. In this register, data is presented 3 symbols at the time to the processor. Every time 3 new valid symbols, received on the SPDIF U Channel are present, the UChannelRxFull interrupt is asserted. For one 98-symbol packet, 96 symbols are carried across SPDIFRxUChannel. To transfer all this data, 32 UChannelRxFull interrupts are generated.
- The QChannelReceive register. In this register, only the Q bit of the packet is accumulated. Operation is similar to UChannelReceive. Because only Q-bit is transferred, only 96 Q-bits are transferred for any 98-symbol packet. To transfer this data, 4 QChannelRxFull interrupts are generated. When QChannelRxFull occurs, it is coincident with UChannelRxFull. There is only one QChannelRxFull for every 8 UChannelRxFull. The convention is that most significant data is transmitted first, and is left-aligned in the registers.
- Timing regarding packet boundary is extracted by hardware. The last UChannelRxFull corresponding to a given packet should be coincident with the last

QChannelRxFull. In this last U, Q channel interrupt, symbols 95-98 are received, Q channel bits 67-98. The interrupts are coincident with UQSyncFound, flagging last symbols of the current frame.

- When the start of the new packet is found before the current packet is complete (less than 98 symbols in the packet), the UQFrameError interrupt is set. The application software should read out UChannelReceive and QchannelReceive registers, discard the value, and assume the start of a new packet.
 - As already said, packet sync extraction is tolerant for single-symbol errors. Packet sync detection is based on the recognition of the sequence data-sync-sync-data in the symbol stream, because this is the only syncing sequence that is not affected by single errors. If the sync symbols are not found 98 symbols after the previous occurrence, it is assumed to be destroyed by channel error, and a new sync symbols is interpolated.
 - Normally, only data bytes are passed to the application software. Every databyte will have its most significant bit set. If sync symbols are passed to the application software, they are seen as all-zero symbols. Sync symbols can only end up in the data stream due to channel error.
- **Behavior of U Channel receive interface on incoming non-CD data.**

This mode is selected if UsyncMode, bit 1 in register CD Text control is set '0'.

In non-CD mode, the SPDIF U channel stream is recognized as a sequence of "data symbols". No packet recognition is done.

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

3 consecutive data symbols seen in the SPDIF U Channel stream are grouped together into the SPDIFRxUChannel register. First symbol is left, last symbol is right aligned. When SPDIFRxUChannel contains 3 new data symbols, UChannelRxFull is asserted.

In this mode, the operation of QchannelRx and associated interrupt QchannelRxFull is reserved, undefined. And the operation of UQFrameError and UQSyncFound is also reserved, undefined.

The U channel is extracted, and output by the SPDIF Rx on SPDIFRxUChannel-Stream.

When incoming SPDIF data parity error or bit error is detected, and if the next SPDIF word for that channel is error-free, the SPDIF word in error is replaced with the average of the previous word and next word. When incoming SPDIF data parity error or bit error is detected, and the next SPDIF word is in error, the previous SPDIF word is repeated.

51.4.1.4 Validity Flag Reception

An interrupt is associated with the Validity flag. (interrupt 16 - SPDIFValNoGood). This interrupt is set every time a frame is seen on the SPDIF interface with the validity bit set to "invalid".

51.4.1.5 SPDIF Receiver Interrupt Exception Definition

Several SPDIF exceptions can trigger an interrupt.

They are:

- Control Status channel change. Set when SPDIFRxCChannel_1 register is updated. The register is updated for every new C-Channel received. The exception is reset on write to InterruptClear register.
- SPDIF Illegal Symbol. Set on reception of illegal symbol during SPDIF receive. Reset by writing register InterruptClear.¹
- SPDIF bit error. Set on reception of bit error. (Parity bit does not match). Reset on write to InterruptClear register.
- Receive data FIFO full. Set when SPDIF receive data FIFO is full.
- Receive data FIFO underrun/overrun. Set when there is a underrun/overrun on the SPDIF receive data FIFO.
- Receive data FIFO resynchronization. Set when a resynchronization event occurs on the SPDIF receive data FIFO.
- Receive U Channel buffer full. Set when next 24 bits of U channel code are available.
- Receive Q Channel buffer overrun. Set when Q channel buffer overrun.
- Receive U Channel buffer overrun. Set on U channel buffer overrun.
- Receive Q Channel buffer full. Set when next 24 bits of Q channel code are available.
- Receive UQ sync found. Set when UQ channel sync found.
- Receive UQ frame error. Set when UQ frame error found.

1. The SPDIF input is a biphas/mark modulated signal. The time between any two successive transitions of the SPDIF signal is always 1, 2 or 3 SPDIF symbol periods long. The SPDIF receiver will parse the stream, and split it in so-called symbols. It recognizes s1, s2 and s3 symbols, depending on the length of the symbols. Not all sequences of these symbols are allowed. To give an example, a sequence s2-s1-s1-s1-s2 cannot occur in a no-error SPDIF signal. If the receiver finds such an illegal sequence, the illegal symbol interrupt is set. No corrective action is undertaken. When the interrupt occurs, this means that(a) The SPDIF signal is destroyed by noise (b) The SPDIF frequency changed.

51.4.1.6 Standards Compliance

The SPDIF interface is compatible with the Tech 3250-E standard of the European Broadcasting Union, except clause 6.3.3 and the IEC60958-3 Ed2 for relevant topics.

Supported input frequency range is 12 KHz up to 96 KHz. (fully compliant) and 96 KHz up to 176 KHz (Can interface with compliant SPDIF transmitter within same cabinet, making reasonable assumptions on jitter added due to interconnecting wire.)

Tolerated jitter on SPDIF input signals are 0.25 bit peak-peak for high frequencies. There is no jitter limit for low frequencies. The user channel extraction in CD mode is capable of coping with single-symbol errors, and still retrieve U channel frames on correct boundaries. This capability is required for reliable reception of CD-Text from some Philips CD channel decoders. This capability was deemed more important than compliance with the IEC60958 annex A.3 standard, and for this reason user channel reception is not compliant with IEC60958 annex A.3. However, the interface is capable to receive U channel inserted by a typical CD channel decoder. Also, in this case, it is more robust and tolerant for channel error than what is required by IEC60958 annex A.3.

51.4.1.7 SPDIF PLOCK Detection and RxcIk Output

Using the high speed system clock, the internal DPLL can extract the bit clock (advanced pulse) from the input bitstream. When this internal DPLL is locked, the LOCK bit of PhaseConfig Register will be set, and the SPDIF Lock output pin SPDIF_LOCK will be asserted.

After DPLL has locked, the pulses are generated, and the average pulse rate is 128 x the sampling frequency. (For a 44.1 KHz input sampling frequency, the average pulse rate = 128 x 44.1 KHz.) The pulse signal is used in the FreqMeas circuit to generate the frequency measurement result.

51.4.1.8 Measuring Frequency of SPDIF_RxCIk

The internal DPLL can extract the bit clock (advanced plus) from the input bitstream. To do that, it is necessary to measure the frequency of the incoming signal in relationship with the system clock (BUS_CLK).

Associated with it are two registers, PhaseConfig and FreqMeas. The circuit will measure the frequency of the incoming clock as a function of the BUS_CLK. The circuit is a second-order filter. The output is a value represented by an unsigned number stored in the 24-bit FreqMeas register, giving the frequency of the source as a function of the BUS_CLK.

$\text{FreqMeas}[23:0] = \text{FreqMeas_CLK} / \text{BUS_CLK} * 2^{10} * \text{GAIN}$.

For example, if the GAIN is selected as $8 * (2^{10})$ ($\text{PhaseConfig}[5:3] = 3'b011$), the actual result

$\text{FreqMeas_CLK} / \text{BUS_CLK}$ is equal to $\text{FreqMeas}[23:0] / 2^{23}$.

51.4.2 SPDIF Transmitter

Audio data for the SPDIF transmitter is provided by processor via the SPDIFTxLeft and SPDIFTxRight registers.

Clocking for SPDIF transmitter is selected through a multiplexer from several clock sources (see [TxClk_Source](#) for clock source inputs). The SPDIF transmitter clock source can be divided down as needed using Txclk_DF. The SPDIF transmitter output can be chosen from either the SPDIF transmitter block, directly from the SPDIF receiver (via the output multiplexer), or disabled.

The SPDIF transmitter generates a SPDIF output bitstream in IEC60958 biphas mark format, consisting of audio data, channel status.

51.4.2.1 Audio Data Transmission

Audio data for the SPDIF transmitter is provided by the processor via SPDIFTxLeft and SPDIFTxRight registers. They send audio data to Tx left and right FIFOs. The Tx left and right FIFOs are also 16-deep and 24-width (equal to the audio data width).

- **SPDIF transmitter data registers - Behavior on overrun, underrun**

The SPDIF Data Transmit registers (SPDIFTxLeft and SPDIFTxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFO. To prevent this from happening, hardware has been added on the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If SPDIF Tx FIFO underruns on the right half of the FIFO, no sample leaves that FIFO (because it was already empty). Special hardware will make sure that the next sample read from the left FIFO will not leave the FIFO (no read strobe is generated). If the underrun occurs on the left half of the FIFO, next read strobe to the right FIFO is blocked.

- **SPDIF transmitter data registers - Automatic resynchronization of FIFOs**

See [Audio Data Reception](#).

- **SPDIFTxLeft, SPDIFTxRight details**

With SPDIF Tx FIFOs three exceptions are associated.

- empty
- under/overrun
- resync

When the empty condition is set for processor data output registers, the processor should write data to the FIFO, before underrun occurs. When empty is set and, for instance, 6 samples need to be written, it is acceptable for the software to write first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. Left should be written before right. The implementation of all data out FIFOs is a double FIFO, one for left and one for right. Empty is set when both FIFOs are empty. Underrun, overrun are set when one of the FIFOs do underrun or do overrun. Resync is set when the hardware resynchronizes left and right FIFOs.

On receiving underrun, overrun interrupt, synchronization between Left and Right words in the FIFOs may be lost. Synchronization will not be lost when the underrun or overrun comes from the IEC60958 side of the FIFO. If the processor reads or writes more data from, for example, left than from right, synchronization will be lost. If automatic resynchronization is enabled, and if the software obeys the rules to let this work, resynchronization will be automatic.

51.4.2.2 Channel Status Transmission

A total of 48 Consumer channel status bits are transmitted from two registers. Channel Status Bits are ordered first bit left.

CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFTxCCchannelCons_h. CS-channel bit "23" is considered bit 0 in the register. C-channel bits 24-47 are seen as MSB-LSB bits of register SPDIFTxCCchannelCons_l.

51.4.2.3 Validity Flag Transmission

The validity bit setting is performed via bit 5 of the SPDIF_SCR register.

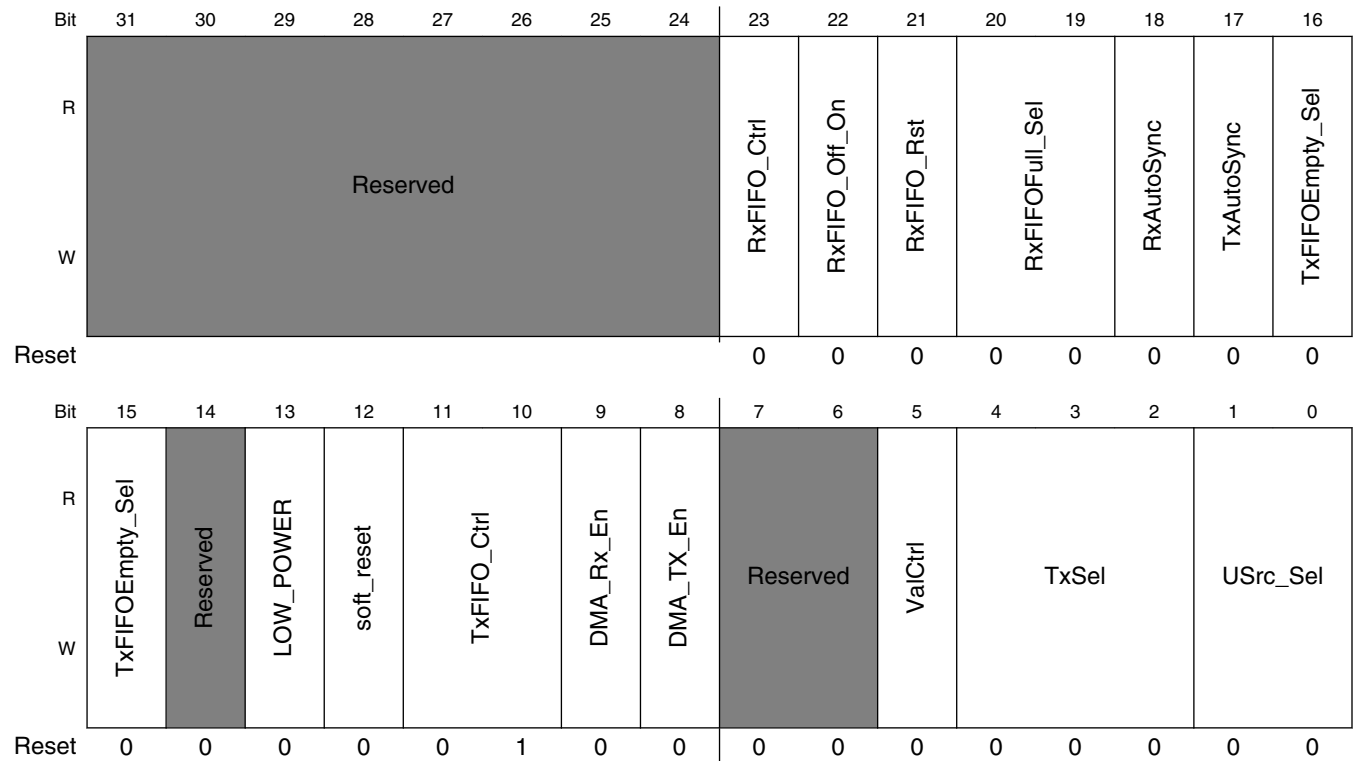

51.5 SPDIF Memory Map/Register Definition

SPDIF memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
200_4000	SPDIF Configuration Register (SPDIF_SCR)	32	R/W	0000_0400h	51.5.1/3266

110	3*(2**10)
Reserved	This read-only field is reserved and always has the value 0.

51.5.4 InterruptEn Register (SPDIF_SIE)

The InterruptEn register (SPDIF_SIE) provides control over the enabling of interrupts.

Address: 200_4000h base + Ch offset = 200_400Ch

SPDIF_SIE field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23 Reserved	This read-only field is reserved and always has the value 0.
22–21 -	This field is reserved. Reserved. set to zero.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overflow

Table continues on the next page...

SPDIF_SIE field descriptions (continued)

Field	Description
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–11 -	This field is reserved. Reserved. set to zero.
10 URxFul	U Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from U Rx reg.
9 URxOv	U Channel receive register overrun
8 QRxFul	Q Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from Q Rx reg.
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
1 TxEm	SPDIF Tx FIFO empty, can't be cleared with reg. IntClear. To clear it, write toTx FIFO.
0 RxFIFOFull	SPDIF Rx FIFO full, can't be cleared with reg. IntClear. To clear it, read from Rx FIFO.

51.5.5 InterruptStat Register (SPDIF_SIS)

The InterruptStat (SPDIF_SIS) register is a read only register that provides the status on interrupt operations.

Address: 200_4000h base + 10h offset = 200_4010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SPDIF_SIS field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–21 Reserved	This read-only field is reserved and always has the value 0.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overflow
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–11 Reserved	This read-only field is reserved and always has the value 0.
10 URxFul	U Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from U Rx reg.
9 URxOv	U Channel receive register overrun
8 QRxFul	Q Channel receive register full, can't be cleared with reg. IntClear. To clear it, read from Q Rx reg.
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overflow
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
1 TxEm	SPDIF Tx FIFO empty, can't be cleared with reg. IntClear. To clear it, write to Tx FIFO.
0 RxFIFOFull	SPDIF Rx FIFO full, can't be cleared with reg. IntClear. To clear it, read from Rx FIFO.

51.5.6 InterruptClear Register (SPDIF_SIC)

The InterruptClear (SPDIF_SIC) register is a write only register and is used to clear interrupts.

Address: 200_4000h base + 10h offset = 200_4010h

SPDIF_SIC field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–21 Reserved	This read-only field is reserved and always has the value 0.
20 Lock	SPDIF receiver's DPLL is locked
19 TxUnOv	SPDIF Tx FIFO under/overflow

Table continues on the next page...

SPDIF_SIC field descriptions (continued)

Field	Description
18 TxResyn	SPDIF Tx FIFO resync
17 CNew	SPDIF receive change in value of control channel
16 ValNoGood	SPDIF validity flag no good
15 SymErr	SPDIF receiver found illegal symbol
14 BitErr	SPDIF receiver found parity bit error
13–10 -	This field is reserved. Reserved.
9 URxOv	U Channel receive register overrun
8 -	Reserved
7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
-	This field is reserved. Reserved.

51.5.7 SPDIFRxLeft Register (SPDIF_SRL)

SPDIFRxLeft register is an audio data reception register.

Address: 200_4000h base + 14h offset = 200_4014h

SPDIF_SRL field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxDataLeft	Processor receive SPDIF data left

51.5.8 SPDIFRxRight Register (SPDIF_SRR)

SPDIFRxRight register is an audio data reception register.

Address: 200_4000h base + 18h offset = 200_4018h

SPDIF_SRR field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxDataRight	Processor receive SPDIF data right

51.5.9 SPDIFRxChannel_h Register (SPDIF_SRC SH)

SPDIFRxChannel_h register is a channel status reception register.

Address: 200_4000h base + 1Ch offset = 200_401Ch

SPDIF_SRCSH field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxCChannel_h	SPDIF receive C channel register, contains first 24 bits of C channel without interpretation

51.5.10 SPDIFRxChannel_I Register (SPDIF_SRCSL)

SPDIFRxChannel_I register is a channel status reception register.

Address: 200_4000h base + 20h offset = 200_4020h

SPDIF_SRCSL field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxCChannel_I	SPDIF receive C channel register, contains next 24 bits of C channel without interpretation

51.5.11 UchannelRx Register (SPDIF_SRU)

UchannelRx register is a user bits reception register.

Address: 200_4000h base + 24h offset = 200_4024h

SPDIF_SRU field descriptions

Field	Description
31–24 [unimplemented]	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
RxUChannel	SPDIF receive U channel register, contains next 3 U channel bytes

51.5.12 QchannelRx Register (SPDIF_SRQ)

QChannelRx register is a user bits reception register.

Address: 200_4000h base + 28h offset = 200_4028h

SPDIF_SRQ field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxQChannel	SPDIF receive Q channel register, contains next 3 Q channel bytes

51.5.13 SPDIFTxLeft Register (SPDIF_STL)

SPDIFTxLeft register is an audio data transmission register.

Address: 200_4000h base + 2Ch offset = 200_402Ch

SPDIF_STL field descriptions

Field	Description
31–24 [unimplemented]	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
TxDataLeft	SPDIF transmit left channel data. It is write-only, and always returns zeros when read

51.5.14 SPDIFTxRight Register (SPDIF_STR)

SPDIFTxRight register is an audio data transmission register.

Address: 200_4000h base + 30h offset = 200_4030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Chapter 52

System Reset Controller (SRC)

52.1 SRC Overview

The System Reset Controller (SRC) controls the reset and boot operation of the SoC.

It is responsible for the generation of all reset signals and boot decoding.

The reset controller determines the source and the type of reset, such as POR, WARM, COLD, and performs the necessary reset qualification and stretching sequences. Based on the type of reset, the reset logic generates the reset sequence for the entire IC. Whenever the chip is powered on, the reset is issued through SRC_ONOFF signal and the entire chip is reset.

52.1.1 Features

The SRC includes the following features.

- Receives and handles the resets from all the reset sources
- Resets the appropriate domains based upon the resets sources and the nature of the reset
- Latches the SRC_BOOT_MODE pins and common configuration signals from the internal fuse

52.2 External Signals

The following table describes the external signals of SRC.

Table 52-1. SRC External Signals

Signal	Description	Pad	Mode	Direction
SRC_BT_CFG0	Boot configuration signals	LCD_DATA00	ALT6	I
SRC_BT_CFG1		LCD_DATA01	ALT6	I

OFF to ON, by timer alarm	<ol style="list-style-type: none"> Timer alarm in SNVS is programmed by software before SoC goes OFF. SoC enters OFF mode. Upon timer limit, wake up alarm goes '0'. PMIC_ON_REQ goes '1'. PMIC receives assertion of PMIC_ON_REQ and wakes up. 	<ol style="list-style-type: none"> Timer alarm in SNVS is programmed by software before SoC goes OFF. SoC enters OFF mode. Upon timer limit, wake up alarm goes '0'. PMIC_ON_REQ goes '1'. External regulator is enabled by PMIC_ON_REQ = 1.

52.5 Power-On Reset and power sequencing

This module generates an internal POR_B signal that is logically AND'ed with any externally applied SRC_POR_B signal. The internal POR_B signal will be held low until all of the following conditions are met:

- 4ms after the external power supply VDDHIGH_IN is valid
- 1ms after the VDD_SOC_CAP supply is valid

The 4ms and 1ms delays are derived from counting the 32 kHz RTC clock cycles; the accuracy depends on the accuracy of the RTC. When the RTC crystal is either absent or in the process of powering up, an internal ring oscillator will be the source of RTC, which is not as accurate as the crystal.

52.5.1 External POR using SRC_POR_B

If the external SRC_POR_B signal is used to control the processor POR, SRC_POR_B must remain low (asserted) until the VDD_ARM_CAP and VDD_SOC_CAP supplies are stable.

52.5.2 Internal POR

If the external SRC_POR_B signal is not used (always held high or left unconnected), the processor defaults to the internal POR function (PMU controls generation of the POR based on the power supplies).

If the internal POR function is used, the following power supply requirements must be met:

- VDD_ARM_IN and VDD_SOC_IN may be supplied from the same source, or
- VDD_SOC_IN can be supplied before VDD_ARM_IN with a maximum delay of 1 ms.

52.6 Functional Description

52.6.1 Reset Control

This section details the reset control of this device.

52.6.1.1 Reset inputs and outputs

The reset control logic receives reset requests from all potential reset sources. All the immediate sources of reset are directly passed to the reset stretching block, whereas the resets requiring qualification are passed on to the reset qualification logic before they are sent to the reset stretching block.

All reset inputs and outputs are described in the following figure:

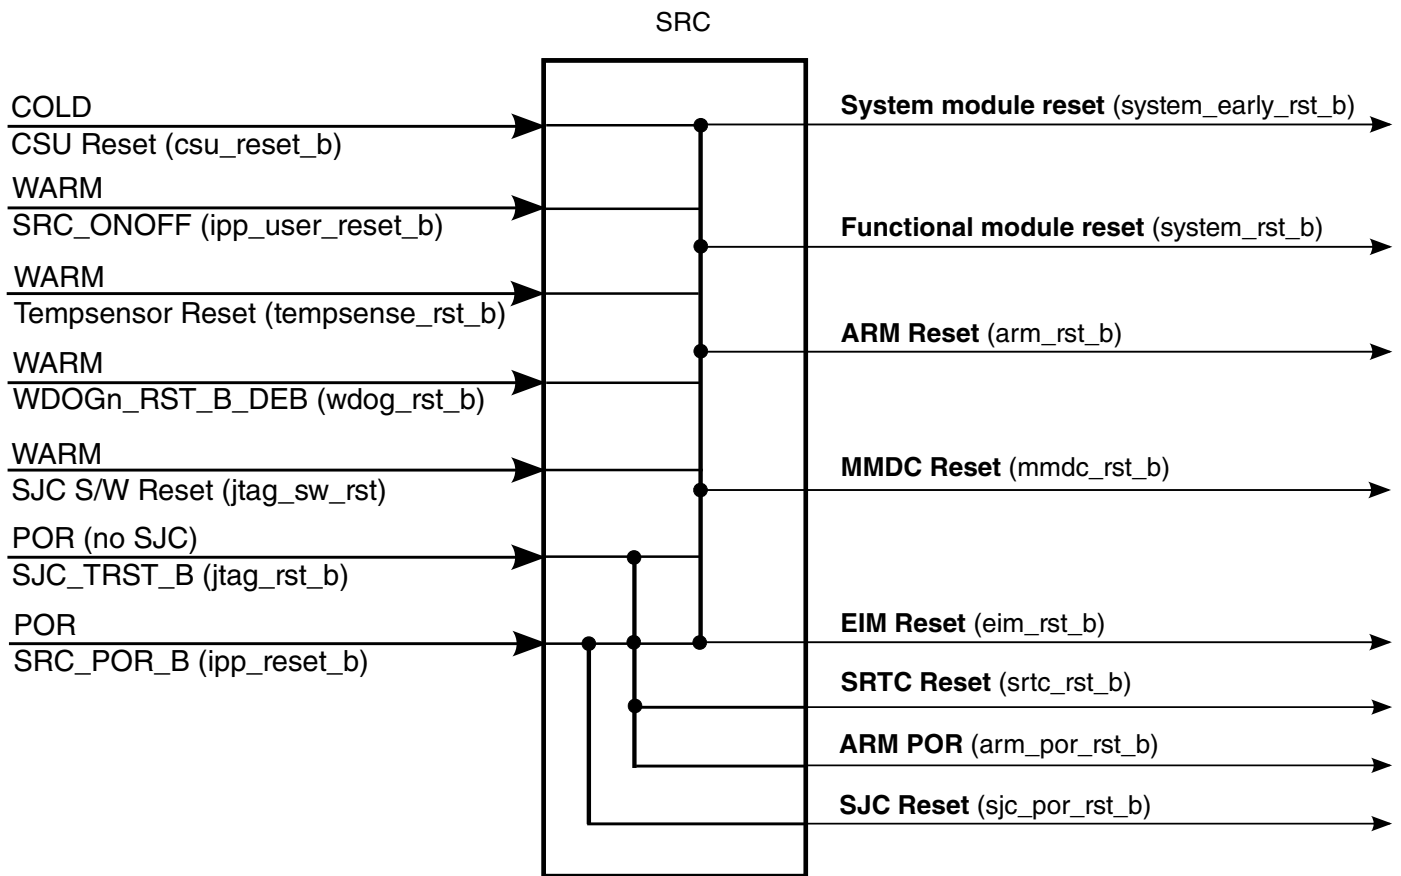

Figure 52-5. SRC inputs and outputs

The reset types and modules they affect are shown in [Table 52-4](#). As there is no chip POR, the POR_B is used to reset the entire chip including test logic and JTAG modules.

NOTE

All resets are expected to be active low except `jtag_sw_rst`.

Table 52-4. SRC reset functionality

SoC Modules	POR	COLD	WARM
System modules (PLLs, fuses, etc)	yes	yes	yes
Functional modules	yes	yes	yes
ARM	yes	yes	yes
ARM SoC	yes	yes	yes
MMDC	yes	yes	yes
ARM POR	yes	no	no
ARM debug	yes	no	no
SJC	yes	no	no
SRTC	yes	no	no

The reset priorities are POR (strongest), COLD and WARM (weakest). If a stronger reset is asserted during the sequence of a weaker reset, then the weaker sequence will be overridden, and the stronger reset sequence will commence. There is no priority within a reset type (POR, etc). If a reset is asserted during the reset sequence of the same type, the reset sequence will be interrupted and restarted.

The following lists the functionality of each of these reset outputs:

- `system_early_rst_b` - Resets the system modules that need to start first as CCM, OCOTP_CTRL, FUSEBOX, MMDC, etc.
- `system_rst_b` - Resets functional modules
- `arm_rst_b` - Resets ARM module (on regular system reset)
- `mmdc_rst_b` - Resets MMDC
- `arm_por_rst_b` - Resets ARM por input
- `arm_soc_rst_b` - Reset for ARM SOC
- `arm_dbg_rst_b` - Reset debug logic of ARM
- `test_logic_rst_b` - Reset test logic (IOMUXC, DAP)
- `sjc_por_rst_b` - Reset to SJC
- `srtc_rst_b` - Resets SRTC

NOTE

It is assumed that each reset source will deassert after its assertion, either due to reset generated to the system from SRC, or by negation of the reset source (if it came from an external source to the chip). In the latter case, the reset source is assumed to be held for at least 2 XTALI clocks so it can be sampled by SRC.

52.6.1.2 Reset Handling

52.6.1.2.1 Reset Qualification

The reset qualification logic qualifies the reset source before sending it out to the chip as a valid reset. WARM resets are in this category. All remaining reset sources are immediate resets and are acknowledged by the reset circuitry the moment they are asserted.

WARM resets are not immediate resets. WARM resets do reset the CCM, the source of MMDC clock. So, if a WARM reset were to immediately reset the CCM, then the MMDC clock would be shut off and this may cause the MMDC data to be lost. During normal mode of operation of the chip, the protocol that is followed before shutting off the

MMDC clock is that an `mmdc_dvfs_req` signal is sent to MMDC and only after the MMDC sends an acknowledge signal, `mmdc_dvfs_ack`, is the clock to the MMDC gated off.

However, the implication here is that a valid WARM reset source condition will not be able to cause a chip reset until the MMDC sends the acknowledge signal (`mmdc_dvfs_ack`). For example, a JTAG reset event has occurred but the JTAG reset will not be serviced until the `mmdc_dvfs_ack` signal is received. So, essentially all WARM reset sources depend on the MMDC providing the `mmdc_dvfs_ack` acknowledge signal before the reset is performed. When the MMDC is not used, `mmdc_dvfs_ack` is defaulted high.

The occurrence of WARM reset results in the assertion of `warm_reset` signal before the system resets are asserted to indicate to the MMDC that the reset occurred is a WARM reset.

A reset source is updated in the Reset Status Register (`SRC_SRSR`) when it becomes valid, provided it is asserted for the minimum amount of time after asserting. So, all immediate resets are immediately updated in the Status Register (`SRC_SRSR`). WARM resets would be updated when the `mmdc_dvfs_ack` signal is received from the MMDC.

Once the reset is qualified, depending on the source of the reset, internal resets are asserted appropriately.

52.6.1.2.2 Reset Sequence and De-Assertion

The `SRC_ONOFF` will assert immediately after any reset source is recognized (except for the case of WARM reset when MMDC needs to answer `mmdc_dvfs_ack` first). After all of the reset sources are released, the SRC will start the following set of events depending on the type of reset that occurred.

52.6.1.2.3 POR (`SRC_POR_B`)

`SRC_POR_B` is an external reset signal. When the chip is powered up, the reset signal is passed through the `POR_B` pin indicating power-up sequence. The SRC resets the entire chip including the JTAG (SJC) module. All SRC registers will be reset during the POR sequence.

As soon as `SRC_POR_B` occurs, all resets are asserted and the entire chip is reset by SRC. The `SRC_POR_B` is stretched for 2 XTALI cycles and the stretching sequence takes place after 2 XTALI clocks of `POR_B` pin deassertion.

The `sjc_por_rst_b` and `srtc_rst_b` signals are deasserted together with `SRC_POR_B` signal. Those outputs are also deasserted after the stretching of `SRC_POR_B` has deasserted.

Once the above resets deassert, `system_early_rst_b` reset is deasserted after 2 XTALI clocks. The `system_early_rst_b` is used for the CCM and PLL-IPs to start generating PLL clock outputs and the system root clocks.

When the system root clocks are ready, the CCM will assert `system_clk_ready` signal. This signal is generated during the start sequence in the CCM and it involves the preparation of the PLLs to generate clock roots for functional operation.

SRC then enables `OCOTP_CTRL` and fusebox clocks, so that fuses can be loaded to `OCOTP_CTRL`.

- SRC will prepare the boot information and then deassert `mmdc_rst_b`.
- SRC will wait 8 ipg clock cycles, and then SRC will enable MMDC clocks.
- SRC will wait 8 XTALI clocks to allow MMDC to generate fixed external clock to external memory SDRAM.
- SRC will enable GPU clocks.
- After 8 ipg cycles, SRC will disable GPU clocks.
- After 8 ipg cycles, resets to all modules will be de-asserted (`system_rst_b`, `gpu_rst_b`).
- After 8 ipg cycles, system clocks will be enabled (`en_system_clk`).

52.6.1.2.4 COLD RESET

The sequence is similar to `SRC_POR_B` except the memory repair operation is not performed.

Once the reset source deasserts, `system_early_rst_b` reset is deasserted after at least 2 XTALI clocks. The `system_early_rst_b` is used for the CCM and PLL-IPs to start generating PLL clock outputs and the system root clocks.

Once the system root clocks are ready, the CCM will assert `system_clk_ready` signal. This signal is generated during the start sequence in the CCM and it involves the preparation of the PLLs to generate clock roots for functional operation. See CCM for more information.

Once `system_clk_ready` arrives at the SRC, it will enable `OCOTP_CTRL` and fusebox clocks, so that fuses can be loaded to `OCOTP_CTRL`. `OCOTP_CTRL` will notify with `iim_ready_flag` once the fusebox loading finishes.

- SRC will prepare the boot information and then deassert `mmdc_rst_b`.
- SRC will wait 8 ipg clock cycles, and then SRC will enable MMDC clocks.

Functional Description

- SRC will wait 8 XTALI clocks to allow MMDC to generate fixed external clock to external memory SDRAM.
- SRC will enable GPU clocks so that reset will penetrate this module.
- After 8 ipg cycles, SRC will disable GPU clocks.
- After 8 ipg cycles resets to all modules will be deasserted (system_rst_b, gpu_rst_b).
- After 8 ipg cycles, system clocks will be enabled (en_system_clk).

52.6.1.2.5 WARM RESET

WARM reset will be enabled only if SRC_SCR[warm_reset_enable] bit is programmed. Otherwise, all WARM reset sources will generate a COLD reset. This bit will be reset only by a POR.

A WARM reset is similar to a COLD reset except that before the reset is sent, a signal to MMDC is asserted `mmdc_dvfs_req` (generates DVFS assertion to MMDC) to request to prepare MMDC to a WARM reset, finishing the transactions placing MMDC in self-refresh. Another signal will be asserted to MMDC (`warm_reset`) that will wrap the WARM reset sequence and will notify MMDC that a WARM reset is in process.

One of the sources of the WARM reset is SRC_ONOFF. If this is the case, it is qualified for 4 XTALI edges. The WARM reset is initiated immediately after 4 XTALI edges. The system does not come out of reset until the the SRC_ONOFF is released.

In case the handshake mechanism with MMDC is stuck, meaning that no `mmdc_dvfs_ack` is received, COLD reset will be generated after a number of XTALI clocks. The number of XTALI clocks is defined in register the SRC_SCR[warm_rst_bypass_count] bitfield (default of this bitfield is 16 XTALI counts.)

The following is a basic description of the WARM reset sequence:

1. ARM sets SRC_SCR[warm_reset_enable] bit to enable the WARM Reset functionality. If this bit is not set, all WARM reset sources will result in COLD reset.
2. Assertion of one of the WARM reset sources.
3. The reset source is qualified in the SRC.
4. If `mmdc_dvfs_ack` signal is low, then SRC triggers the MMDC to switch to self-refresh mode using `mmdc_dvfs_req` signal. This is done through the CCM to combine with the DVFS sent from the CCM in case of frequency change of MMDC.
5. Wait for `mmdc_dvfs_ack` signal from the MMDC. If no ack is received during `warm_rst_bypass_count` number of XTALI clocks, COLD reset will be generated.
6. Assert `warm_reset` signal to MMDC.
7. SRC asserts system resets

The deassertion sequence is exactly the same as in the Cold Reset except waiting for 8 XTALIs for MMDC to generate fixed external clock to external memory MMDC. This stage is not needed in WARM reset since MMDC is held in self-refresh in WARM reset and there is no need to reconfigure it when exiting WARM reset.

WARM BOOT

Software can save any needed information in the memory before initiating a WARM reset. In this case, software will set SRC_SRSR[warm_boot] bit before initiating WARM reset. After the system returns to run mode, the warm_boot bit will still be set, indicating the software that data was saved in memory and can be reused.

NOTE

mmdc_dvfs_req and acknowledge during WARM reset can be masked in the CCM by configuration of register CCCR[17:16].

52.6.2 Parallel Reset Requests

SRC will follow the following rules in the case of parallel reset requests:

1. The order of strength of resets is POR - strongest, cold - medium, warm - weakest.
2. If a stronger reset is asserted during weaker reset sequence, then the stronger reset will take over and the stronger reset process will commence. The following cases fall into this category:
 - POR reset request in the middle of cold or warm reset process - the cold or warm reset process will be stopped and the POR sequence will start.
 - COLD reset request in the middle of warm reset process - the warm reset process will be stopped and the cold sequence will start.
3. If a weaker reset is asserted during stronger reset sequence, then the stronger reset sequence will continue without interference. If at the end of the stronger reset process the weaker request is still asserted then the weaker sequence will commence. The following cases fall into this category:
 - COLD or WARM reset requests in the middle of POR reset process - the POR process will continue without interference.
 - WARM reset request in the middle of COLD reset process - the COLD process will continue without interference.
4. If a similar reset request is asserted during the process of reset handling, then the process of reset handling will start over (with the same process). The following cases fall into this category:

Functional Description

- POR reset request in the middle of POR reset process - the POR process will start over.
- COLD reset request in the middle of COLD reset process - the COLD process will start over.

There is one exception to this category: WARM reset request in the middle of WARM reset process. In this case, the new WARM reset process cannot restart because MMDC is reset and there can't be a handshake with MMDC if it is reset. In this case the first WARM reset will continue, and only if the second WARM reset is still asserted after the first one has finished, the WARM sequence will start again.

52.6.3 Boot Mode Control

52.6.3.1 BOOT_MODE Pin Latching

The exact boot sequence is controlled by the values of the BOOT_MODE pins on this device.

The value of the BOOT_MODE pins will be latched after the OCOTP_CTRL asserts the fuse read completion flag. After latching, the values of the BOOT_MODE pins are used to determine the booting options of the core as described in the SRC_SBMRx registers.

The boot mode general purpose bits can be provided to the SRC from either e-fuses or GPIO signals. The gpio_bt_sel e-fuse defines the source to be used to derive the boot information. When gpio_bt_sel is set, e-fuses are used. When cleared, GPIO signals are used.

The boot information is provided in SRC_SBMR1 register. The figure below shows the selection of boot mode information.

NOTE

BOOT_MODE[1:0] inputs of SRC are connected to BOOT_MODE[1:0] pins.

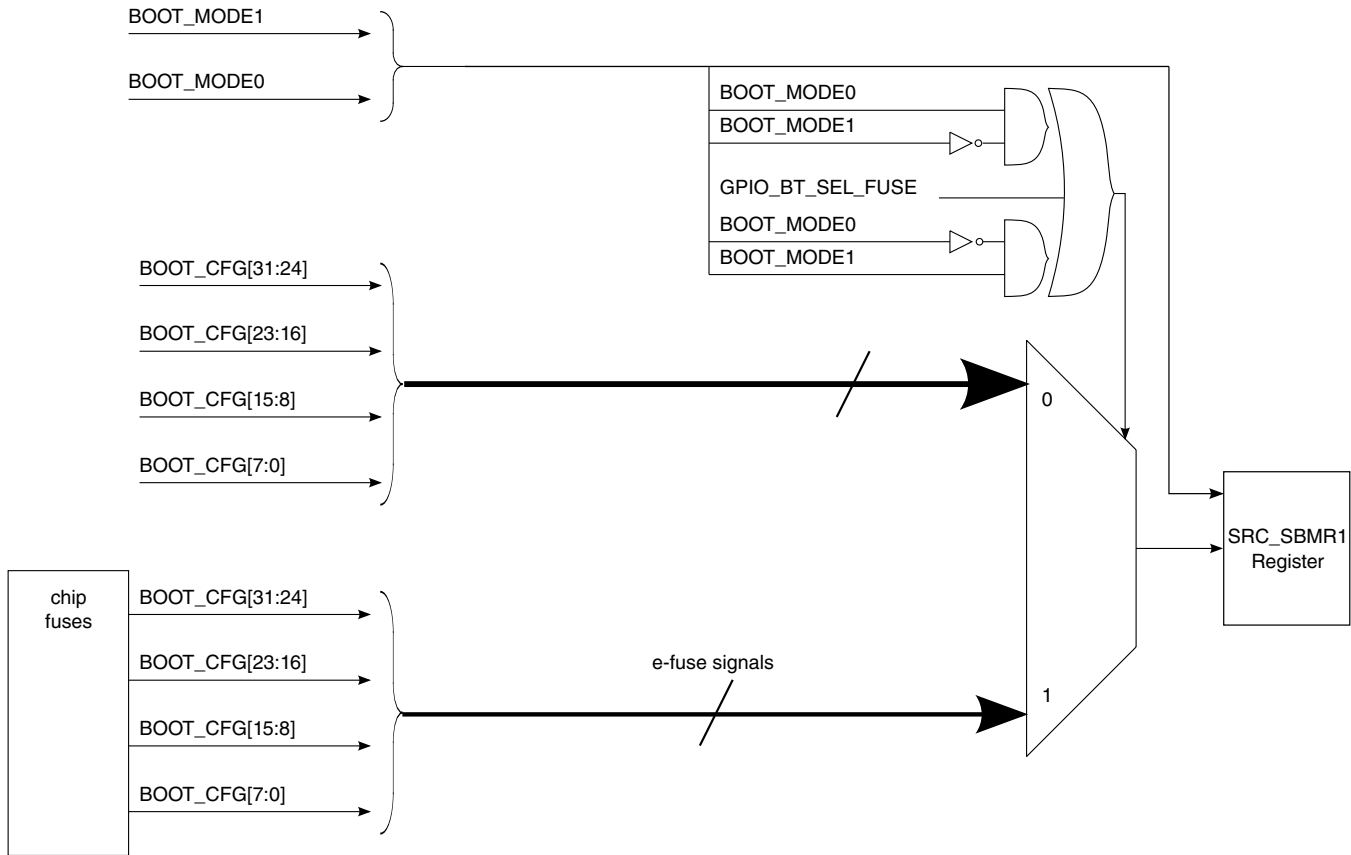

Figure 52-6. Boot mode information

52.7 SRC Memory Map/Register Definition

SRC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

52.7.1 SRC Control Register (SRC_SCR)

The Reset control register (SCR), contains bits that control operation of the reset controller.

Address: 20D_8000h base + 0h offset = 20D_8000h

SRC_SCR field descriptions

Field	Description
31–28 mask_wdog3_rst	<p>Mask wdog3_rst_b source. If these 4 bits are coded from A to 5 then, the wdog3_rst_b input to SRC will be masked and the wdog3_rst_b will not create a reset to the chip.</p> <p>NOTE: During the time the WDOG3 event is masked using SRC logic, it is likely that the WDOG3 Reset Status Register (WRSR) bit 1 (which indicates a WDOG3 timeout event) will get asserted. Software / OS developer must prepare for this case. Re-enabling the WDOG3 is possible, by unmasking it in SRC, though it must be preceded by servicing the WDOG3. However, for the case that the event has been asserted, the status bit (WRSR bit-1) will remain asserted, regardless of servicing the WDOG3 module.</p> <p>NOTE: Hardware reset is the only way to cause the de-assertion of that bit. Any other code than 0101 will be coded to 1010 i.e. wdog3_rst_b is not masked</p> <p>0101 wdog3_rst_b is masked 1010 wdog3_rst_b is not masked</p>
27–26 mix_rst_strch	<p>SoC mix (Audio, ENET, uSDHC, EIM, QSPI, OCRAM, MMDC, etc) power up reset stretch mix reset width = (mix_rst_strch +1)* 88 ipg_clk cycles</p> <p>00 mix reset width is 88 ipg_cycle cycles 01 mix reset width is 2 * 88 ipg_cycle cycles 10 mix reset width is 3 * 88 ipg_cycle cycles 11 mix reset width is 4 * 88 ipg_cycle cycles</p>
25 dbg_rst_msk_pg	<p>Do not assert debug resets after power gating event of core</p> <p>0 do not mask core debug resets (debug resets will be asserted after power gating event) 1 mask core debug resets (debug resets won't be asserted after power gating event)</p>
24 wdog3_rst_optn	<p>Wdog3_rst_b option</p> <p>0 Wdog3_rst_b asserts M4 reset (default) 1 Wdog3_rst_b asserts global reset</p>
23–22 Reserved	This read-only field is reserved and always has the value 0.
21 cores_dbg_rst	<p>Software reset for debug of arm platform only.</p> <p>NOTE: This is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared.</p> <p>0 do not assert arm platform debug reset 1 assert arm platform debug reset</p>
20–18 Reserved	This read-only field is reserved and always has the value 0.
17 core0_dbg_rst	<p>Software reset for core0 debug only.</p> <p>NOTE: This is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared.</p> <p>0 do not assert core0 debug reset 1 assert core0 debug reset</p>
16–14 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

SRC_SCR field descriptions (continued)

Field	Description
13 core0_rst	<p>Software reset for core0 only.</p> <p>NOTE: This is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared.</p> <p>0 do not assert core0 reset 1 assert core0 reset</p>
12 -	<p>This field is reserved. Reserved</p>
11 eim_rst	<p>EIM reset is needed in order to reconfigure the eim chip select.</p> <p>The software reset bit must de-asserted.</p> <p>The eim chip select configuration should be updated.</p> <p>The software bit must be re-asserted since this is not self-refresh.</p>
10–7 mask_wdog_rst	<p>Mask wdog_rst_b source. If these 4 bits are coded from A to 5 then, the wdog_rst_b input to SRC will be masked and the wdog_rst_b will not create a reset to the chip.</p> <p>NOTE: During the time the WDOG event is masked using SRC logic, it is likely that the WDOG Reset Status Register (WRSR) bit 1 (which indicates a WDOG timeout event) will get asserted. software / OS developer must prepare for this case. Re-enabling the WDOG is possible, by unmasking it in SRC, though it must be preceded by servicing the WDOG. However, for the case that the event has been asserted, the status bit (WRSR bit-1) will remain asserted, regardless of servicing the WDOG module.</p> <p>(Hardware reset is the only way to cause the de-assertion of that bit). any other code will be coded to 1010 i.e. wdog_rst_b is not masked</p> <p>0101 wdog_rst_b is masked 1010 wdog_rst_b is not masked (default)</p>
6–5 warm_rst_ bypass_count	<p>Defines the XTALI cycles to count before bypassing the MMDC acknowledge for WARM reset. If the MMDC acknowledge will not be asserted before this counter has elapsed, then a COLD reset will be initiated.</p> <p>00 Counter not to be used - system will wait until MMDC acknowledge until it is asserted. 01 Wait 16 XTALI cycles before changing WARM reset to a COLD reset. 10 Wait 32 XTALI cycles before changing WARM reset to a COLD reset. 11 Wait 64 XTALI cycles before changing WARM reset to a COLD reset</p>
4–1 -	<p>This field is reserved. Reserved</p>
0 warm_reset_ enable	<p>WARM reset enable bit. WARM reset will be enabled only if warm_reset_enable bit is set. Otherwise all WARM reset sources will generate COLD reset.</p> <p>0 WARM reset disabled 1 WARM reset enabled</p>

52.7.2 SRC Boot Mode Register 1 (SRC_SBMR1)

The Boot Mode register (SBMR) contains bits that reflect the status of Boot Mode Pins of the chip. The reset value is configuration dependent (depending on boot/fuses/IO pads).

If SRC_GPR10[28] bit is set, this bit instructs the ROM code to use the SRC_GPR9 register as if it is SBMR1. This allows software to override the fuse bits and boot from an alternate boot source.

Address: 20D_8000h base + 4h offset = 20D_8004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15–8 BOOT_CFG2[7:0]	Refer to fusemap.
BOOT_CFG1[7:0]	Refer to fusemap.

52.7.3 SRC Reset Status Register (SRC_SRSR)

The SRSR is a write to one clear register which records the source of the reset events for the chip. The SRC reset status register will capture all the reset sources that have occurred. This register is reset on ipp_reset_b. This is a read-write register.

For bit[6-0] - writing zero does not have any effect. Writing one will clear the corresponding bit. The individual bits can be cleared by writing one to that bit. When the system comes out of reset, this register will have bits set corresponding to all the reset sources that occurred during system reset. Software has to take care to clear this register by writing one after every reset that occurs so that the register will contain the information of recently occurred reset.

SRC_SRSR field descriptions

Field	Description
31–17 Reserved	This read-only field is reserved and always has the value 0.
16 warm_boot	<p>WARM boot indication shows that WARM boot was initiated by software. This indicates to the software that it saved the needed information in the memory before initiating the WARM reset. In this case, software will set this bit to '1', before initiating the WARM reset. The warm_boot bit should be used as indication only after a warm_reset sequence. Software should clear this bit after warm_reset to indicate that the next warm_reset is not performed with warm_boot. Please refer to Reset Sequence and De-Assertion for details on warm_reset.</p> <p>0 WARM boot process not initiated by software. 1 WARM boot initiated by software.</p>
15–9 Reserved	This read-only field is reserved and always has the value 0.
8 tempense_rst_b	Temper Sensor software reset. Indicates whether the reset was the result of software reset from on-chip Temperature Sensor.

Table continues on the next page...

SRC_SRSR field descriptions (continued)

Field	Description
	0 Reset is not a result of software reset from Temperature Sensor. 1 Reset is a result of software reset from Temperature Sensor.
7 wdog3_rst_b	IC Watchdog3 Time-out reset. Indicates whether the reset was the result of the watchdog3 time-out event. 0 Reset is not a result of the watchdog3 time-out event. 1 Reset is a result of the watchdog3 time-out event.
6 jtag_sw_rst	JTAG software reset. Indicates whether the reset was the result of software reset from JTAG. 0 Reset is not a result of software reset from JTAG. 1 Reset is a result of software reset from JTAG.
5 jtag_rst_b	HIGH - Z JTAG reset. Indicates whether the reset was the result of HIGH-Z reset from JTAG. 0 Reset is not a result of HIGH-Z reset from JTAG. 1 Reset is a result of HIGH-Z reset from JTAG.
4 wdog_rst_b	IC Watchdog Time-out reset. Indicates whether the reset was the result of the watchdog time-out event. 0 Reset is not a result of the watchdog time-out event. 1 Reset is a result of the watchdog time-out event.
3 ipp_user_reset_b	Indicates whether the reset was the result of the ipp_user_reset_b qualified reset. 0 Reset is not a result of the ipp_user_reset_b qualified as COLD reset event. 1 Reset is a result of the ipp_user_reset_b qualified as COLD reset event.
2 csu_reset_b	Indicates whether the reset was the result of the csu_reset_b input. NOTE: If case the csu_reset_b occurred during a WARM reset process, during the phase that ipg_clk is not available yet, then the occurrence of CSU reset will not be reflected in this bit. 0 Reset is not a result of the csu_reset_b event. 1 Reset is a result of the csu_reset_b event.
1 Reserved	This read-only field is reserved and always has the value 0.
0 ipp_reset_b	Indicates whether reset was the result of ipp_reset_b pin (Power-up sequence) 0 Reset is not a result of ipp_reset_b pin. 1 Reset is a result of ipp_reset_b pin.

52.7.4 SRC Interrupt Status Register (SRC_SISR)

Address: 20D_8000h base + 14h offset = 20D_8014h

SRC_SISR field descriptions

Field	Description
31–9 Reserved	This read-only field is reserved and always has the value 0.
8–6 Reserved	This read-only field is reserved and always has the value 0.
5 core0_wdog_rst_ req	WDOG reset request from core0. Read-only status bit.
-	This field is reserved. Reserved

52.7.5 SRC Boot Mode Register 2 (SRC_SBMR2)

The Boot Mode register (SBMR), contains bits that reflect the status of Boot Mode Pins of the chip. The default values for those bits depends on the values of pins/fuses during reset sequence, hence the question mark on their default value.

Address: 20D_8000h base + 1Ch offset = 20D_801Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0						BMOD[1:0]		0

Chapter 53

Temperature Monitor (TEMPMON)

53.1 Overview

The temperature sensor module implements a temperature sensor/conversion function based on a temperature-dependent voltage to time conversion.

The module features alarm functions that can raise independent interrupt signals if the temperature is above two high-temperature thresholds and below a low temperature threshold. These temperature thresholds are programmable and designated as low, high and panic temperature. The panic threshold is a special programmable threshold in that if the temperature increases above this value and the temperature-panic-reset interrupt is enabled in the System Reset Controller, the hardware will assume that software no longer has control over the thermal situation and will initiate a reset of the chip.

In order to avoid false panic temperature initiated resets, the panic alarm will not fire until the temperature panic condition has been met for four consecutive conversion cycles. A self-repeating mode can also be programmed which executes a temperature sensing operation based on a programmed delay.

Since the high and low temperature thresholds are programmable, they form a sliding temperature bracket that can be tailored to the application's needs. For example, at start-up software can set the low temperature threshold to the minimum temperature code and the high temperature threshold to a maximum operating temperature for the system.

The system can then use this module to monitor the on-die temperature and take appropriate actions such as throttling back the core frequency when a the high temperature interrupt is set. Once the high temperature interrupt is set then the system can program the low temperature threshold to a desired cool down temperature. The system would then switch to monitoring the low temperature alarm and wait for its interrupt to be set. With this scheme, once the low temperature interrupt is set then software could be assured that the temperature has cooled down to a safe level and the process could be repeated.

The high-level implementation of the temperature sensor is shown in the figure below.

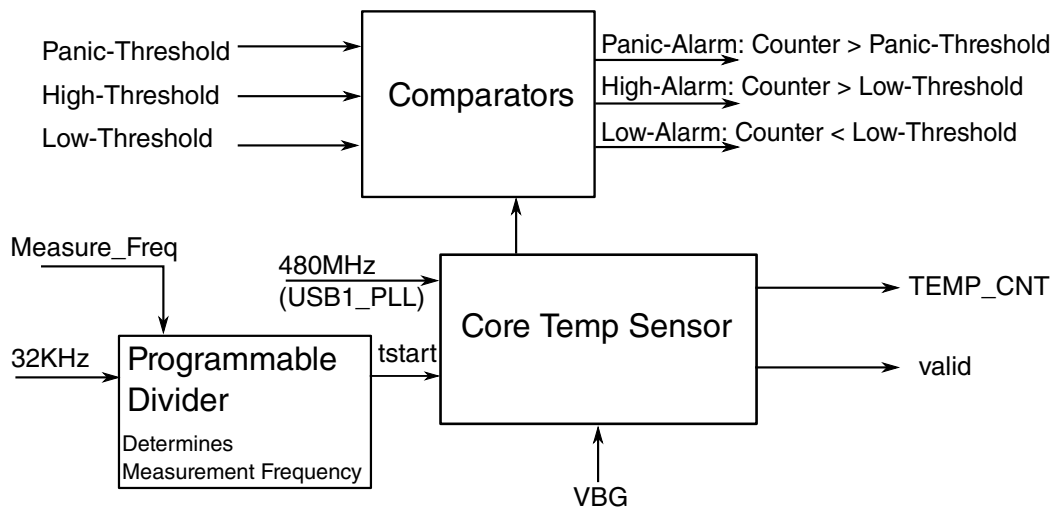

Figure 53-1. High Level Temp Sensor System Diagram

As shown in the figure above, the temperature sensor uses and assumes that the bandgap reference, 480MHz PLL and 32KHz RTC modules are properly programmed and fully settled for correct operation.

53.2 Software Usage Guidelines

During normal system operation software can use the temperature sensor counter output (TEMP_CNT) in conjunction with the fused temperature calibration data to determine the on-die operational temperature or to set an over-temperature interrupt alarm to within a couple of °C.

Based on calibration, two sets of temperature and counter values will be available via fuses on the device. These data points will correspond to the points (N₁, T₁) and (N₂, T₂) in the curve below.

Figure 53-2. Temperature Measurement Cycle

After a temperature measurement cycle, software should use the calibration points in conjunction with the temperature code value in the `TEMPMON_TEMPSENSE0[TEMP_CNT]` bitfield to calculate the temperature for the device using the following equation:

$$T_{\text{meas}} = T_2 - (N_{\text{meas}} - N_2) * ((T_2 - T_1) / (N_1 - N_2))$$

Likewise, to determine the alarm counter value to be written in the `TEMPMON_TEMPSENSE0` register for a temperature based interrupt, the above equation can be solved for the N_{meas} value that should be used based on the desired temperature trigger.

The temperature calibration point fuse values are available in the `OCOTP_ANA1` register. The temperature calibration values are fused individually for each part in the product testing process. The fields of this register are described in the following table.

Table 53-1. OCOTP_ANA1 Temperature Sensor Calibration Data

Bit Range	Bit Mask	Name	Description
[31:20]	FFF0_0000h	ROOM_COUNT	Value of <code>TEMPMON_TEMPSENSE0[TEMP_VALUE]</code> after a measurement cycle at room temperature (25.0 °C).
[19:8]	000F_FF00h	HOT_COUNT	Value of <code>TEMPMON_TEMPSENSE0[TEMP_VALUE]</code> after a measurement cycle at the hot temperature, i.e. <code>HOT_TEMP</code> .
[7:0]	0000_00FFh	HOT_TEMP	The hot temperature test point. Each LSB equals 1 °C.

The points on the calibration curve are as follows.

- $(N_1, T_1) = (\text{ROOM_COUNT}, 25.0)$

TEMPMON Memory Map/Register Definition

- $(N_2, T_2) = (\text{HOT_COUNT}, \text{HOT_TEMP})$
- $(N_{\text{meas}}, T_{\text{meas}}) = (\text{TEMP_CNT}, T_{\text{meas}})$

Substituting the fields from OCOTP_ANA1 into the earlier equation results in the following:

$$T_{\text{meas}} = \text{HOT_TEMP} - (N_{\text{meas}} - \text{HOT_COUNT}) * ((\text{HOT_TEMP} - 25.0) / (\text{ROOM_COUNT} - \text{HOT_COUNT}))$$

53.3 TEMPMON Memory Map/Register Definition

TEMPMON memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
20C_8180	Tempsensor Control Register 0 (TEMPMON_TEMPSENSE0)	32	R/W	0000_0001h	53.3.1/3319

53.3.1 Tempensor Control Register 0 (TEMPMON_TEMPSENSE0n)

This register defines the basic controls for the temperature sensor minus the frequency of automatic sampling which is defined in the tempsensor.

Address: 20C_8000h base + 180h offset + (4d × i), where i=0d to 3d

TEMPMON Memory Map/Register Definition

TEMPMON_TEMPSENSE0n field descriptions

Field	Description
31–20 ALARM_VALUE	This bit field contains the temperature count (raw sensor output) that will generate an alarm interrupt.
19–8 TEMP_CNT	This bit field contains the last measured temperature count.
7 -	This field is reserved. Reserved.
6 -	This field is reserved. Reserved.
5–3 -	This field is reserved. Reserved
2 FINISHED	Indicates that the latest temp is valid. This bit should be cleared by the sensor after the start of each measurement. 0 INVALID — Last measurement is not ready yet. 1 VALID — Last measurement is valid.
1 MEASURE_TEMP	Starts the measurement process. If the measurement frequency is zero in the TEMPSENSE1 register, this results in a single conversion.

Table continues on the next page...

TEMPMON_TEMPSENSE0n field descriptions (continued)

Field	Description
	0 STOP — Do not start the measurement process. 1 START — Start the measurement process.
0 POWER_DOWN	This bit powers down the temperature sensor. 0 POWER_UP — Enable power to the temperature sensor. 1 POWER_DOWN — Power down the temperature sensor.

**53.3.2 Tempensor Control Register 1
(TEMPMON_TEMPSENSE1n)**

This register defines the automatic repeat time of the temperature sensor.

Address: 20C_8000h base + 190h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

TEMPMON_TEMPSENSE1n field descriptions

Field	Description
31–16 -	This field is reserved. Reserved.
MEASURE_ FREQ	This bits determines how many RTC clocks to wait before automatically repeating a temperature measurement. The pause time before remeasuring is the field value multiplied by the RTC period. 0x0000 Defines a single measurement with no repeat. 0x0001 Updates the temperature value at a RTC clock rate. 0x0002 Updates the temperature value at a RTC/2 clock rate. ... — 0xFFFF Determines a two second sample period with a 32.768KHz RTC clock. Exact timings depend on the accuracy of the RTC clock.

53.3.3 Tempensor Control Register 2 (TEMPMON_TEMPSENSE2n)

This register defines the automatic repeat time of the temperature sensor.

Address: 20C_8000h base + 290h offset + (4d × i), where i=0d to 3d

TEMPMON_TEMPSENSE2n field descriptions

Field	Description
31–28 -	This field is reserved. Reserved
27–16 PANIC_ALARM_VALUE	This bit field contains the temperature that will generate a panic interrupt when exceeded by the temperature measurement.
15–12 -	This field is reserved. Reserved.
LOW_ALARM_VALUE	This bit field contains the temperature that will generate a low alarm interrupt when the field is greater than the temperature measurement.

Chapter 54

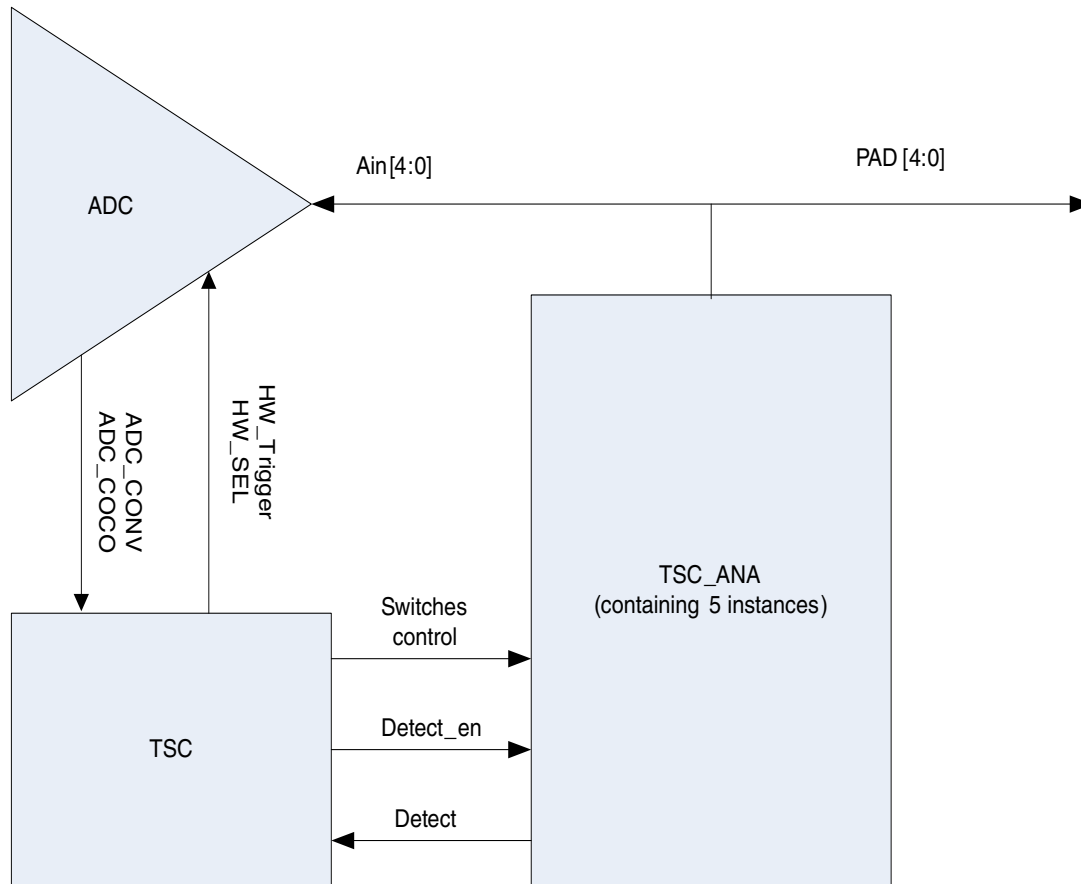

Touch Screen Controller (TSC)

54.1 Overview

This block describes the Touch Screen Controller (TSC), which is used for ADC and touch screen analogue block.

TSC is responsible for providing control of ADC and touch screen analogue block to form a touch screen system, which achieves function of touch detection and touch location detection. The controller utilizes ADC hardware trigger function and control switches in touch screen analogue block. The controller only supports 4-wire or 5-wire screen touch modes.

Figure 54-1. TSC block diagram

54.1.1 Features

The features of TSC controller are following.

- Configure registers: 32-bit, fully support sky-blue bus interface
- 4-wire or 5-wire mode of touch screen
- Low power wake up functions
- ADC average function and custom 8-bit, 10-bit, and 12-bit conversion result
- Custom pre-charge and de-glitch threshold time setting
- Total control five analogue groups of switches
- Fully asynchronous interface to ADC and analogue switches
- Easy software operation
- Software takes control of operation flow
- Strong debug functions—enable software recognize the IP as a transparent box and operation output directly
- Software reset function

54.2 Functional Description

This block works with ADC and TSC analogue to form a touch screen system. The system is responsible to detect touch on screen and measure the coordinate of the touch point. The touch screen controller, which is at the heart of the system, given control to TSC analogue and ADC. TSC analogue provides positive or negative voltage to the screen if the touch screen controller provides relevant signals. The ADC convert coordinates value if requested by touch screen controller.

54.2.1 Operating modes

The TSC can be worked in the following modes.

54.2.1.1 Idle

The TSC always stays at idle status if finish a coordinate measurement. The TSC only starts to detect a touch or starts to measure coordinate value if set the start_sen bit. The TSC returns to idle status after finish current task if disable bit is set by software.

54.2.1.2 Pre-charge

Pre-charge is a preparation for detection stage. Before detection stage, the upper layer of screen is required to charge to positive high. The time required for the pre-charge can be set in the pre-charge_timer.

54.2.1.3 Detection

Detection is a stage to sense touch detect on the screen. This stage is initialed a delay (set by pre-charge_timer) in order to wait enough time for the lower screen layer to achieve even-potential status. After the TSC send out detect enable signal to detect signal from analogue, once receiving the signal, TSC starts to measure coordinates or waiting for the instruction from software according to the value of auto_measure. If auto_measure is set then the TSC automatically measures coordinates after detect a touch. Otherwise TSC

waits for software order after detects a touch (and generates an interrupt). The software can choose to drop the measure (and return back to idle) by setting `drop_measure`, or start the measure by setting `start_measure`.

54.2.1.4 Measurement

During the measure stage, the TSC hardware gives control to TSC analogue and ADC. No software operation is needed. If requesting average function, do average configuration for ADC.

54.2.1.5 Data valid check

After measure the coordinate value, TSC do a touch detects again. If no touch has been detected, then previous measured coordinates' value is invalid. Otherwise, the measured coordinates' value is valid.

54.2.1.6 Interrupt

Each interrupt provides three software interface bits: interrupt enable, interrupt signal enable, and interrupt signal.

54.2.1.7 Reset

The TSC has two resets: `ipg_reset_b` and `sw_rst`. The `ipg_reset_b` reset is a hardware reset, which resets all registers in TSC block. While the `sw_rst` is a software reset, which resets every register except ips directly access ones.

54.2.1.8 Debug mode

The TSC provides fully software control signals. Once `debug_en` has been set, then all TSC outputs will be controlled by software. Software can also observe all TSC inputs through debug interface. Furthermore, the debug registers also provides current state machine states. Software can always check the current hardware state.

54.2.2 Configuration

54.2.2.1 TSC configurations

The following tables provide 4-wire and 5-wire screen touch modes.

Table 54-1. 4-wire screen touch mode

	wiper	ynlr	ypil	xnur	xpul
X measurement	OFF	OFF	OFF	LOW	HIGH
Y measurement	OFF	LOW	HIGH	OFF	OFF
Pre-charge	OFF	OFF	OFF	HIGH (200K, PULL UP)	HIGH (200K, PULL UP)
Intermediate	OFF	OFF	OFF	OFF	HIGH (200K)
Touch screen dection	OFF	LOW	LOW	OFF	HIGH (200K)

Table 54-2. 5-wire screen touch mode

	wiper	ynlr	ypil	xnur	xpul
X measurement	OFF	LOW	HIGH	LOW	HIGH
Y measurement	OFF	LOW	LOW	HIGH	HIGH
Pre-charge	HIGH (200K, PULL UP)	OFF	OFF	OFF	OFF
Intermediate¹	HIGH (200K)	OFF	OFF	OFF	OFF
Touch screen dection	HIGH (200K)	LOW	LOW	OFF	OFF

1. All other intermediate states switche to OFF.

54.2.2.2 TSC-ADC-TSC analogue configuration

The touch screen controller needs to co-work with ADC and TSC analogue.

The ADC is responsible for analogue value conversion. Following tables show the channels that the ADC used.

Table 54-3. 4-wire screen touch mode

X measurement	Channel 1	Connects to TSC ana YNLR
---------------	-----------	--------------------------

Table continues on the next page...

Table 54-3. 4-wire screen touch mode (continued)

Y measurement	Channel 3	Connects to TSC ana YNUR
---------------	-----------	--------------------------

Table 54-4. 5-wire screen touch mode

X measurement	Channel 0	Connects to TSC ana WIPER
Y measurement	Channel 0	Connects to TSC ana WIPER

54.2.2.3 TSC, TSC analogue and ADC connection

The following table describes the connections among the TSC, TSC analogue, and ADC.

Table 54-5. TSC, TSC analogue and ADC connection

TSC controller ports	TSC analogue IP ports	TSC analogue system integration instance Name	ADC Ain ports
wiper_pull_up	pu_en	1	Ain [0]
wiper_200k_pull_up	pull_up_200k_en		
wiper_pull_down	pd_en		
ynlr_pull_up	pu_en	2	Ain [1]
ynlr_200k_pull_up	pull_up_200k_en		
ynlr_pull_down	pd_en		
ypll_pull_up	pu_en	3	Ain [2]
ypll_200k_pull_up	pull_up_200k_en		
ypll_pull_down	pd_en		
xnur_pull_up	pu_en	4	Ain [3]
xnur_200k_pull_up	pull_up_200k_en		
xnur_pull_down	pd_en		
xpul_pull_up	pu_en	5	Ain [4]
xpul_200k_pull_up	pull_up_200k_en		
xpul_pull_down	pd_en		

54.2.2.4 TSC and GPIO

From TSC point of view, it does not care what kinds of PAD used. It can use digital pad or analogue pad.

Table 54-6. The ports used in TSC and GPIO

TSC function ports	TSC analogue instance	ADC Ain pin	GPIO ports
wiper	1	Ain [0]	GPIO1_IO00
ynlr	2	Ain [1]	GPIO1_IO01
ypll	3	Ain [2]	GPIO1_IO02
xnur	4	Ain [3]	GPIO1_IO03
xpul	5	Ain [4]	GPIO1_IO04

NOTE

For the PAD used for TSC, make sure the PAD behavior , such as a wire only connects to the Pin and TSC analogue switches.

For the PAD used for GPIO, for example, has a keeper to prevent the GPIO pad working from a wire only connects the Pin and TSC. In such condition, disable keeper when TSC working.

54.2.2.5 ADC-TSC co-working

The TSC is designed to work with the ADC. Two IP must work together to achieve the correct functions. The coordinate work includes two steps:

1. TSC starts ADC

TSC sends two signals: trigger and hardware trigger select signal: HWTS[4:0].

ADC regards triggers as clock to capture the select signal: HWTS. The details of information about trigger and HWTS is show in the ADC hardware trigger chapter. The TSC hardware makes sure that the HWTS signals ready one clock cycles before sending trigger signals. Make sure that the trigger delay is less than HWTS delay + one clock cycle.

The TSC send HWTS as in the following table:

	TSC 4-wire mode	TSC 5-wire mode
x-coordinate measure	HWTS = 5'b01000	HWTS = 5'b10000
y-coordinate measure	HWTS = 5'b00010	HWTS = 5'b10000

TSC HWTS[4:0] connects to the ADC HWTS[4:0]. The integration change will lead change in driver implementation. On ADC side, HWTS = 1 << x indicates the x logic channel is selected to start hardware ADC conversion. Configure ADC_HC_x to configure x logic channel and conversion will store in ADC_R_x.

Each ADC hardware trigger logic channel can be configured to one of many physical channels. The details of the ADC configuration, refer to the ADC hardware trigger chapter. Software driver configures the physical ADC. A sample configuration is shown in the following table.

	TSC 4-wire mode	TSC 5-wire mode
x-coordinate measure	ADC measures channel 1 or 2, so configure ADC_HC3[ADCH] to 1 or 2.	ADC measure channel 0, so configure ADC_HC[4] to 0.
y-coordinate measure	ADC measures channel3 or 4, so configure ADC_HC1[ADCH] to 3 or 4.	ADC measures channel 0, so configure ADC_HC[4] to 0.

Before TSC starts work, software driver configure ADC_HC_x. TSC hardware automatically sends trigger and HWTS at the correct time.

2. ADC sends back converted value and complete signals to TSC.

When ADC finishes conversion, the ADC would send a complete signal to TSC. A set of handshake signals between ADC and TSC makes sure that the TSC could receive complete signals, store correct ADC converted value, and clear ADC coco signals at correct order. All parts of this step are automatically done by hardware.

NOTE

For different ADC conversion modes, such 8-bit, 10-bit, 12-bit mode, average mode, please configure in ADC registers.

54.3 TSC Memory Map/Register Definition

The TSC Memory Map and Register Definition is described in the following section.

TSC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
204_0000	PS Input Buffer Address (TSC_BASIC_SETTING)	32	R/W	0000_0000h	54.3.1/3331
204_0010	PS Input Buffer Address (TSC_PS_INPUT_BUFFER_ADDR)	32	R/W	0000_0000h	54.3.2/3332

Table continues on the next page...

TSC memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
204_0020	Flow Control (TSC_FLOW_CONTROL)	32	R/W	0000_0000h	54.3.3/3333
204_0030	Measure Value (TSC_MEASURE_VALUE)	32	R	0000_0000h	54.3.4/3334
204_0040	Interrupt Enable (TSC_INT_EN)	32	R/W	0000_0000h	54.3.5/3335
204_0050	Interrupt Signal Enable (TSC_INT_SIG_EN)	32	R/W	0000_0000h	54.3.6/3336
204_0060	Interrupt Status (TSC_INT_STATUS)	32	R/W	0000_0000h	54.3.7/3337
204_0070	TSC_DEBUG_MODE	32	R/W	0000_0000h	54.3.8/3339
204_0080	TSC_DEBUG_MODE2	32	R/W	0000_0000h	54.3.9/3341

54.3.1 PS Input Buffer Address (TSC_BASIC_SETTING)

Address: 204_0000h base + 0h offset = 204_0000h

TSC_BASIC_SETTING field descriptions

Field	Description
31–8 MEASURE_DELAY_TIME	Measure Delay Time Before X-axis or Y-axis measurement, the screen need some time before even potential distribution ready.
7–5 Reserved	This read-only field is reserved and always has the value 0.
4 4_5_WIRE	4/5 Wire detection 4-Wire Detection Mode or 5-Wire Detection Mode 0 4-Wire Detection Mode 1 5-Wire Detection Mode

Table continues on the next page...

TSC_BASIC_SETTING field descriptions (continued)

Field	Description
3-1 Reserved	This read-only field is reserved and always has the value 0.
0 AUTO_MEASURE	Auto Measure This field indicates after detect touch, whether automatic start measurement. SW must make sure that the detect interrupt should be disable. This bit is not HW self-clear. 0 Disable Auto Measure 1 Auto Measure

54.3.2 PS Input Buffer Address (TSC_PS_INPUT_BUFFER_ADDR)

Address: 204_0000h base + 10h offset = 204_0010h

TSC_PS_INPUT_BUFFER_ADDR field descriptions

Field	Description
PRE_CHARGE_TIME	Auto Measure This field indicates after detect touch, whether automatic start measurement. SW must make sure that the detect interrupt should be disable. This bit is not HW self-clear. 0 Disable Auto Measure 1 Auto Measure

54.3.3 Flow Control (TSC_FLOW_CONTROL)

Address: 204_0000h base + 20h offset = 204_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															DISABLE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0		START_SENSE	0				DROP_MEASURE	0			START_MEASURE	0			SW_RST
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TSC_FLOW_CONTROL field descriptions

Field	Description
31–17 Reserved	This read-only field is reserved and always has the value 0.
16 DISABLE	This bit is for SW disable registers. After set this bit, the hardware returns to idle status after finish the current state operation. SW must check the SW_IDLE bit to confirm that the controller has return to idle status. It's a HW self-clean bit. 0 Leave HW state machine control 1 SW set to idle status
15–13 Reserved	This read-only field is reserved and always has the value 0.
12 START_SENSE	Start Sense It's a HW self-clean bit. 0 Stay at idle status 1 Start sense detection and (if auto_measure set to 1) measure after detect a touch
11–9 Reserved	This read-only field is reserved and always has the value 0.
8 DROP_MEASURE	Drop Measure This field indicates whether start measure X/Y coordinate value after detect a touch It's a HW self-clean bit. 0 Do not drop measure for now 1 Drop the measure and controller return to idle status

Table continues on the next page...

TSC_FLOW_CONTROL field descriptions (continued)

Field	Description
7-5 Reserved	This read-only field is reserved and always has the value 0.
4 START_MEASURE	Start Measure This field indicates whether start measure X/Y coordinate value after detect a touch It's a self-clean bit. 0 Do not start measure for now 1 Start measure the X/Y coordinate value
3-1 Reserved	This read-only field is reserved and always has the value 0.
0 SW_RST	Soft Reset This is a synchronization reset, which reset all HW registers. NOTE: All SW accessible registers would keep as it original setting Software reset would be self-clear.

54.3.4 Measure Value (TSC_MEASEURE_VALUE)

Address: 204_0000h base + 30h offset = 204_0030h

TSC_MEASEURE_VALUE field descriptions

Field	Description
31-28 Reserved	This read-only field is reserved and always has the value 0.
27-16 X_VALUE	X Value Coordinate value NOTE: It is an ADC conversion value, SW need to convert it to fit screen size.
15-12 Reserved	This read-only field is reserved and always has the value 0.
Y_VALUE	Y Value Y coordinate value, note, it is an ADC conversion value, SW need to convert it to fit screen size

54.3.5 Interrupt Enable (TSC_INT_EN)

Address: 204_0000h base + 40h offset = 204_0040h

TSC_INT_EN field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 IDLE_SW_INT_EN	<p>Idle Software Interrupt Enable</p> <p>This field indicates whether enable the software return to idle status interrupt. This interrupt is generated if the controller has return to idle status. This bit is only valid if disable bit in flow control register set to 1'b1.</p> <p>0 Disable idle software interrupt 1 Enable idle software interrupt</p>
11–5 Reserved	<p>Reserved</p> <p>This read-only field is reserved and always has the value 0.</p>
4 DETECT_INT_EN	<p>Detect Interrupt Enable</p> <p>This field indicates whether enable the detect interrupt. This interrupt is generated if there is a touch detect after pre-charge ready.</p> <p>0 Disable detect interrupt 1 Enable detect interrupt</p>
3–1 Reserved	This read-only field is reserved and always has the value 0.
0 MEASURE_INT_EN	<p>Measure Interrupt Enable</p> <p>This field indicates whether enable the measure interrupt. This interrupt is generated after the touch detection which follows measurement.</p> <p>0 Disable measure</p>

54.3.6 Interrupt Signal Enable (TSC_INT_SIG_EN)

Address: 204_0000h base + 50h offset = 204_0050h

TSC_INT_SIG_EN field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 IDLE_SW_SIG_EN	<p>Idle Software Signal Enable</p> <p>This field indicates whether enable the software return to idle status. This signal is generated if the controller has return to idle status. This bit is only valid if disable bit in flow control register set to 1'b1.</p> <p>0 Disable idle software signal 1 Enable idle software signal</p>
11–9 Reserved	This read-only field is reserved and always has the value 0.
8 VALID_SIG_EN	<p>Valid Signal Enable</p> <p>This field indicates whether enable the valid signal. This field generated at the same time with MEASURE_SIG_EN.</p> <p>0 Disable valid signal 1 Enable valid signal</p>
7–5 Reserved	This read-only field is reserved and always has the value 0.
4 DETECT_SIG_EN	<p>Detect Signal Enable</p> <p>This field indicates whether enable the detect signal.</p> <p>0 Disable detect signal 1 Enable detect signal</p>

Table continues on the next page...

TSC_INT_SIG_EN field descriptions (continued)

Field	Description
3–1 Reserved	This read-only field is reserved and always has the value 0.
0 MEASURE_SIG_EN	Measure Signal Enable This field indicates whether enable the measure signal.

54.3.7 Interrupt Status (TSC_INT_STATUS)

Address: 204_0000h base + 60h offset = 204_0060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W	[Shaded]

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0			IDLE_SW	0				VALID	0			DETECT	0		MEASURE
W	[Shaded]			[Shaded]	[Shaded]				[Shaded]	[Shaded]			[Shaded]	[Shaded]		[Shaded]
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TSC_INT_STATUS field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 IDLE_SW	Idle Software This field indicates whether the state machine return to idle status. This signal is generated if the controller has return to idle status. This bit is only valid if disable bit in flow control register set to 1'b1. 0 Haven't return to idle status 1 Already return to idle status
11–9 Reserved	This read-only field is reserved and always has the value 0.
8 VALID	Valid Signal This field indicates whether the measure value is valid. This field generated at the same time with MEASURE_SIG. 0 There is no touch detected after measurement, indicates that the measured value is not valid 1 There is touch detection after measurement, indicates that the measure is valid
7–5 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

TSC_INT_STATUS field descriptions (continued)

Field	Description
4 DETECT	Detect Signal This field indicates whether there is a detect signal. 0 Does not exist a detect signal 1 Exist detect signal
3-1 Reserved	This read-only field is reserved and always has the value 0.
0 MEASURE	Measure Signal This field indicates whether there is a measure signal. 0 Does not exist a measure signal 1 Exist a measure signal

54.3.8 TSC_DEBUG_MODE

Address: 204_0000h base + 70h offset = 204_0070h

TSC_DEBUG_MODE field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28 DEBUG_EN	<p>Debug Enable</p> <p>The RO registers in debug_mode and debug_mode2 always reflect the latest value and is not controlled by this bit. All RW SW bits are controlled by this bit.</p> <p>0 Enable debug mode 1 Disable debug mode</p>
27 Reserved	This read-only field is reserved and always has the value 0.
26 ADC_COCO_ CLEAR_ DISABLE	<p>ADC COCO Clear Disable</p> <p>This bit could prevent TSC HW generates an ADC COCO clear signal.</p> <p>NOTE: This bit does not effect ADC_COCO_CLEAR bit.</p> <p>0 Allow TSC hardware generates ADC COCO clear 1 Prevent TSC from generate ADC COCO clear signal — —</p>
25 ADC_COCO_ CLEAR	<p>ADC Coco Clear</p> <p>Original ADC coco only clear is system read conv result from IPS bus. However, TSC read conv result directly from ADC to lower SW load, so that ADC requires TSC generates a clear signal.</p> <p>0 No ADC COCO clear 1 Set ADC COCO clear</p>
24 TRIGGER	<p>Trigger</p> <p>Hardware trigger signal to ADC</p> <p>0 No hardware trigger signal 1 Hardware trigger signal, the signal must last at least 1 ips clock period</p>
23–21 Reserved	This read-only field is reserved and always has the value 0.
20–16 EXT_HWTS	<p>Hardware Trigger Select Signal</p> <p>Hardware trigger select signal, select which channel to start conversion.</p>
15–13 Reserved	This read-only field is reserved and always has the value 0.
12 ADC_COCO	<p>ADC COCO Signal</p> <p>This signal is generated by ADC.</p>
ADC_CONV_ VALUE	<p>ADC Conversion Value</p> <p>This signal is generated by ADC.</p>

Chapter 55

TrustZone Address Space Controller (TZASC)

55.1 Overview

The TrustZone Address Space Controller (TZASC) protects security-sensitive SW and data in a trusted execution environment against potentially compromised SW running on the platform.

The TZASC block diagram is shown in figure below.

Figure 55-1. TZASC Block Diagram

The TZASC is an IP by ARM ("CoreLink™ TrustZone Address Space Controller TZC-380"), designed to provide configurable protection over program (SW) memory space.

The main features of TZASC are:

- Supports 16 independent address regions
- Access controls are independently programmable for each address region
- Sensitive registers may be locked
- Host interrupt may be programmed to signal attempted access control violations

- AXI master/slave interfaces for transactions
- APB slave interface for configuration and status reporting

55.2 Clocks

The table found here describes the clock sources for TZASC.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 55-1. TZASC Clocks

Clock name	Clock Root	Description
ackl	mmdc_axi_clk_root	Module clock

55.3 Address Mapping in various memory mapping modes

The address configured to the TZASC controller(s) must match the "local addresses" as being passed on to the DDR controller(s).

Memory "aliasing" implications on TZASC settings - in systems which does not utilize the maximal supported DDR space the controller is designed for, the whole DDR memory map becomes "aliased" (replicated) by the size of the physical memory used. In such cases, the TZASC must be configured to protect all aliased regions as well (i.e. effectively reducing the number of available TZASC regions, since all aliased regions must be handled, for each "real" space needing protection).

For complete details on TZASC functionality and the programming model, see the ARM document, "CoreLink™ TrustZone Address Space Controller TZC-380 Technical Reference Manual, (Rev r0p1 or newer)", available at <http://infocenter.arm.com>.

Chapter 56

Universal Asynchronous Receiver/Transmitter (UART)

56.1 Overview

Universal Asynchronous Receiver/Transmitter (UART) provides serial communication capability with external devices through a level converter and an RS-232 cable or through use of external circuitry that converts infrared signals to electrical signals (for reception) or transforms electrical signals to signals that drive an infrared LED (for transmission) to provide low speed IrDA compatibility.

UART supports NRZ encoding format , RS485 compatible 9 bit data format and IrDA-compatible infrared slow data rate (SIR) format.

The following figure is the UART block diagram.

The "Module Clock" is the UART_CLK which comes from CCM. The "Peripheral Clock" is the IPG_CLK which comes from CCM.

Figure 56-1. UART Block Diagram

56.1.1 Features

The UART includes the following features:

- High-speed TIA/EIA-232-F compatible, up to 5.0 Mbit/s
- Serial IR interface low-speed, IrDA-compatible (up to 115.2 Kbit/s)
- 9-bit or Multidrop mode (RS-485) support (automatic slave address detection)
- 7 or 8 data bits for RS-232 characters, or 9 bit RS-485 format
- 1 or 2 stop bits
- Programmable parity (even, odd, and no parity)
- Hardware flow control support for request to send (RTS_B) and clear to send (CTS_B) signals
- RS-485 driver direction control via CTS_B signal
- Edge-selectable RTS_B and edge-detect interrupts
- Status flags for various flow control and FIFO states
- Voting logic for improved noise immunity (16x oversampling)
- Transmitter FIFO empty interrupt suppression
- UART internal clocks enable/disable

- Auto baud rate detection (up to 115.2 Kbit/s)
- Receiver and transmitter enable/disable for power saving
- RX_DATA input and TX_DATA output can be inverted respectively in RS-232/RS-485 mode
- DCE/DTE capability
- RTS_B, IrDA asynchronous wake (AIRINT), receive asynchronous wake (AWAKE), RI_B (DTE only), DCD_B (DTE only), DTR_B (DCE only) and DSR_B (DTE only) interrupts wake the processor from STOP mode
- Maskable interrupts
- Two DMA Requests (TxFIFO DMA Request and Rx FIFO DMA Request)
- Escape character sequence detection
- Software reset (SRST_B)
- Two independent, 32-entry FIFOs for transmit and receive
- The peripheral clock can be totally asynchronous with the module clock. The module clock determines baud rate. This allows frequency scaling on peripheral clock (such as during DVFS mode) while remaining the module clock frequency and baud rate.

56.1.2 Modes of operation

- Serial RS-232NRZ mode
- 9-bit RS-485 mode
- IrDA mode

To set UART in different modes, see the table below.

Table 56-1. UART mode definition

MDEN (UMCR[0])	IREN (UCR1[7])	UART Mode	Description
0	0	RS-232	RXD/TXD data is serial RS-232 NRZ format
0	1	IrDA (Interface)	RXD/TXD data is IrDA-compatible infrared slow data rate (SIR) format
1	0	RS-485	RXD/TXD data is RS485 compatible 9 bit data format
1	1	Undefined	Undefined

56.2 External Signals

Tables that lists the conventions for representing signals and describing all UART signals that connect off-chip can be found here.

External Signals

The chip-level IOMUX modifies the direction and routing of the UART signals based on whether the UART is operating in DCE mode (UARTn_UFCR[DCEDTE]=0) or DTE mode (UARTn_UFCR[DCEDTE]=1). The routing of the external signals to the UART module is shown in the figure below.

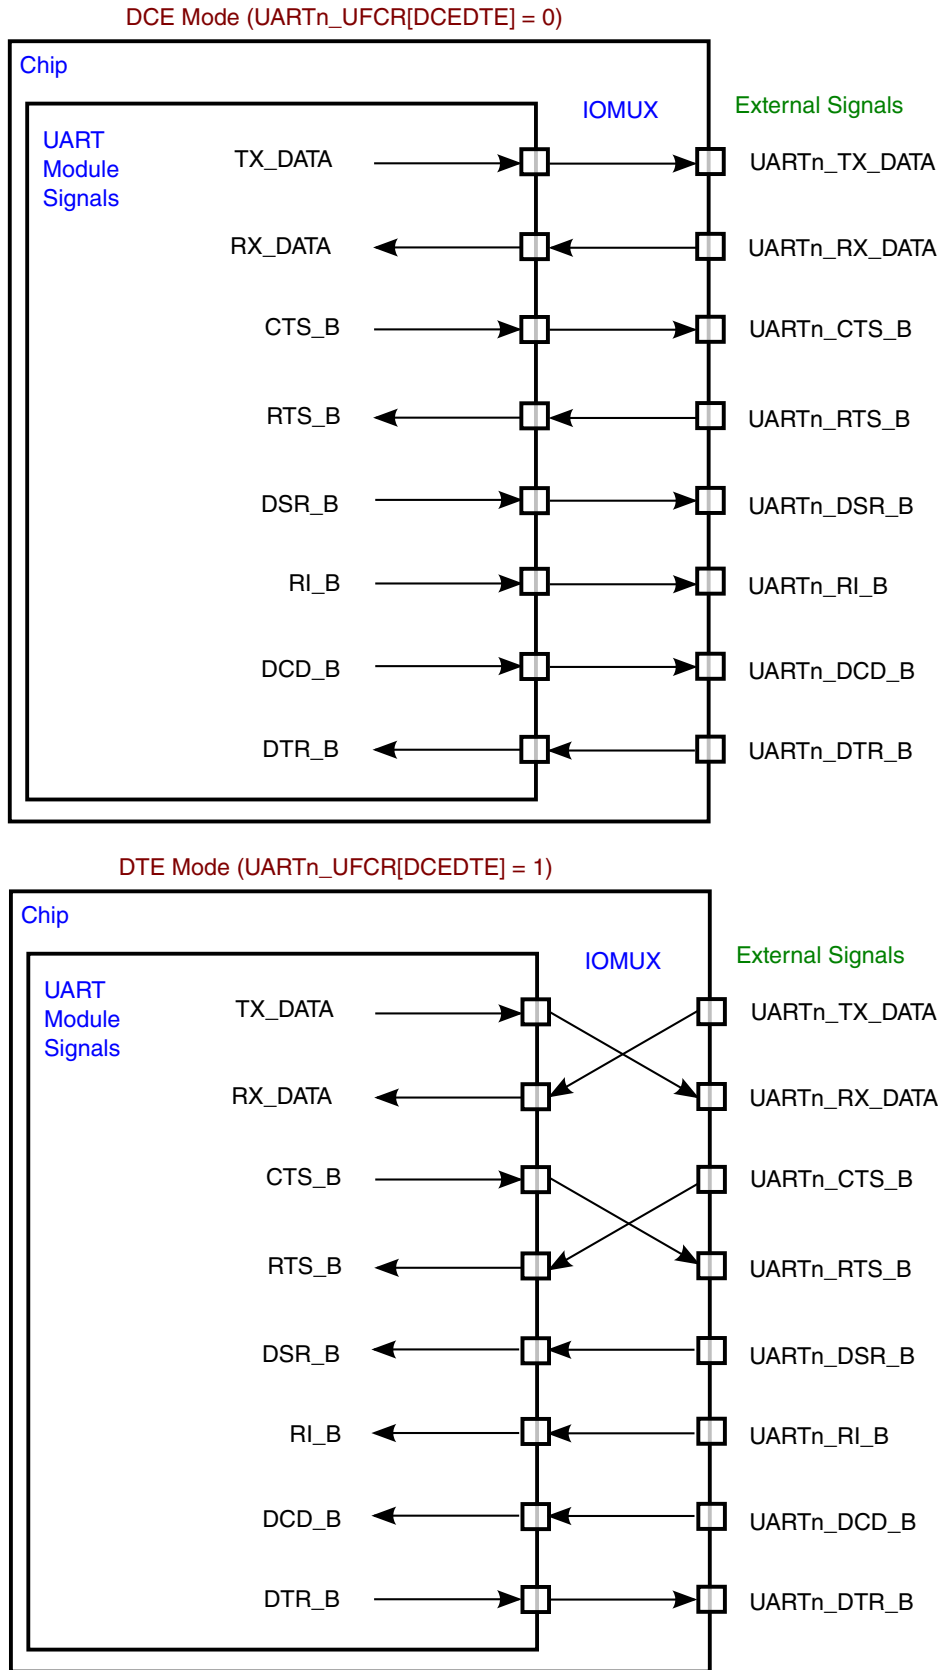

Figure 56-2. UART external signals to module signals routing with respect to DCE/DTE mode

External Signals

The following tables describes the external signals of UART:

Table 56-2. UART External Signals

Signal	Description	Pad	Mode	Direction
UART1_CTS_B	Clear to send	GPIO1_IO06	ALT8	I
		UART1_CTS_B	ALT0	
UART1_RTS_B	Request to send	GPIO1_IO07	ALT8	O

		ENET2_RX_DATA1	ALT1	
UART6_TX_DATA	Serial / infrared data transmit	CSI_MCLK	ALT8	I
		ENET2_RX_DATA0	ALT1	
UART7_CTS_B	Clear to send	ENET1_TX_CLK	ALT1	I
		LCD_DATA06	ALT1	
UART7_RTS_B	Request to send	ENET1_RX_ER	ALT1	O
		LCD_DATA07	ALT1	
UART7_RX_DATA	Serial / infrared data receive	ENET2_TX_DATA0	ALT1	O
		LCD_DATA17	ALT1	
UART7_TX_DATA	Serial / infrared data transmit	ENET2_RX_EN	ALT1	I
		LCD_DATA16	ALT1	
UART8_CTS_B	Clear to send	ENET2_TX_CLK	ALT1	I
		LCD_DATA04	ALT1	
UART8_RTS_B	Request to send	ENET2_RX_ER	ALT1	O
		LCD_DATA05	ALT1	
UART8_RX_DATA	Serial / infrared data receive	ENET2_TX_EN	ALT1	O
		LCD_DATA21	ALT1	
UART8_TX_DATA	Serial / infrared data transmit	ENET2_TX_DATA1	ALT1	I
		LCD_DATA20	ALT1	

The user must configure the input path to the UART by properly configuring the DAISY bits in the IOMUXC_UARTn_RX_DATA_INPUT and the IOMUXC_UARTn_UART_RTS_B_SELECT_INPUT registers.

For IOMUXC_UARTn_UART_RTS_B_SELECT_INPUT[DAISY]:

- Configurations that select UARTn_RTS_B for the pad are only valid when UARTn_UFCR[DCEDTE]=0 (DCE mode)
- Configurations that select UARTn_CTS_B for the pad are only valid when UARTn_UFCR[DCEDTE]=1 (DTE mode)

For IOMUXC_UARTn_UART_RX_DATA_B_SELECT_INPUT[DAISY]:

- Configurations that select UARTn_RX_DATA for the pad are only valid when UARTn_UFCR[DCEDTE]=0 (DCE mode)
- Configurations that select UARTn_TX_DATA for the pad are only valid when UARTn_UFCR[DCEDTE]=1 (DTE mode)

56.2.1 Detailed Signal Descriptions

56.2.1.1 Interrupt Signals

56.2.1.1.1 *interrupt_uart* - UART Interrupt

Output interrupt request.

56.2.1.2 DMA Request Signals

56.2.1.2.1 *dma_req_rx* - Receiver DMA Request

Output DMA Request signal for receiver interface.

56.2.1.2.2 *dma_req_tx* - Transmitter DMA Request

Output DMA Request signal for transmitter interface. Set at 0 when TXDMAEN (UCR1[3]) is at 1 and TRDY (USR1[13]) is also at 1.

56.2.1.3 Special Signals

56.2.1.3.1 *stop_req* - Stop Mode

Input stop mode. Indicates to UART that ARM platform is going to enter in Stop Mode and clocks are going to stop running.

See [Low Power Modes](#) for more information about Stop Mode.

56.2.1.3.2 *doze_req* - Doze Mode

Input doze mode. ARM platform requests UART to switch in doze mode (power saving mode).

See [Low Power Modes](#) for more information about Doze Mode.

56.2.1.3.3 *debug_req* - Debug Mode

Input debug mode. Indicates UART it has to enter in debug mode.

See [UART Operation in System Debug State](#), for more information about Debug Mode.

56.3 Clocks

The table found here describes the clock sources for UART.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 56-3. UART Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_s	ipg_clk_root	Peripheral access clock
ipg_perclk	uart_clk_root	Module clock

56.4 Functional Description

This section provides a complete functional description of the block.

56.4.1 Interrupts and DMA Requests

See the following table for the lists of all interrupt and DMA signals and associated interrupt and DMA sources of the UART. See register description section for explanation of interrupt/DMA enable and status.

Table 56-4. Interrupts and DMA

Interrupt/DMA Output	Interrupt/DMA Enable	Enable Register Location	Interrupt/DMA Flag	Flag Register Location
<i>interrupt_uart</i>	RRDYEN	UCR1 (bit 9)	RRDY	USR1 (bit 9)
	IDEN	UCR1 (bit 12)	IDLE	USR2 (bit 12)
	DREN	UCR4 (bit 0)	RDR	USR2 (bit 0)
	RXDSEN	UCR3 (bit 6)	RXDS	USR1 (bit 6)

<i>dma_req_rx</i>	RXDMAEN	UCR1 (bit 8)	RRDY	USR1 (bit 9)
	ATDMAEN	UCR1 (bit 2)	AGTIM	USR1 (bit 8)
	IDDMAEN	UCR4 (bit 6)	IDLE	USR2 (bit 12)
<i>dma_req_tx</i>	TXDMAEN	UCR1 (bit 3)	TRDY	USR1 (bit 13)

56.4.2 Clocks

This section describes clocks and special clocking requirements of the UART.

56.4.2.1 Clock requirements

UART module receives 2 clocks, *peripheral_clock* and *module_clock*. The *peripheral_clock* is used as write clock of the TxFIFO, read clock of the RxFIFO and synchronization of the modem control input pins. It must always be running when UART is enabled. There is an exception in stop mode (see [Clocking in Low-Power Modes](#)).

The *module_clock* is for all the state machines, writing RxFIFO, reading TxFIFO, etc. It must always be running when UART is sending or receiving characters. This clock is used in order to allow frequency scaling on *peripheral_clock* without changing configuration of baud rate (*module_clock* staying at a fixed frequency).

The constraints on *peripheral_clock* and *module_clock* are as follows:

- *peripheral_clock* and *module_clock* can totally be asynchronous. They can also be synchronous.
- Due to the 16x oversampling of the incoming characters, *module_clock* frequency must always be greater or equal to 16x the maximum baud rate. For example, if max baud rate is 4 Mbit/s, *module_clock* must be greater or equal to $4 \text{ M} \times 16 = 64 \text{ MHz}$.

NOTE

The restriction that *peripheral_clock* frequency must be higher or equal to 16x baud rate has been removed. There is no limitation on *peripheral_clock* frequency to baud rate.

56.4.2.2 Maximum Baud Rate

The max baud rate the UART can support is determined by the max frequency of the *module_clock*.

For example, if the SoC can provide the fastest *module_clock* 66.5 MHz, the UART can transmit and receive serial data with the maximum baud rate $66.5\text{M}/16 = 4.15 \text{ Mbit/s}$.

The UART supports serial IR interface low speed. In the low speed IrDA mode, the max baud rate is 115.2 Kbit/s. To support the 115.2 Kbit/s, *module_clock* frequency must be higher or equal to 1.8432 MHz.

56.4.2.3 Clocking in Low-Power Modes

The UART supports 2 low-power modes: DOZE and STOP.

In STOP mode (input pin *stop_req* is at '1'), the UART doesn't need any clock. In this mode the UART can wake-up the ARM platform with the asynchronous interrupts (see [Low Power Modes](#)).

- If before entering in STOP mode the software has enabled RTSDEN interrupt, when RTS will change state (put at '0' by external device started to send), the asynchronous interrupt will wake-up the system, *peripheral_clock* and *module_clock* will be provided to the UART before first start bit, so that no data will be lost.
- If RTS doesn't change state (already at '0' before entering in STOP mode), then wake-up interrupt (AWAKE) will be sent at the arrival of first Start bit (on falling edge). In this case, the UART must receive the *peripheral_clock* and *module_clock* during the first half of start bit to correctly receive this character (for example, at 115.2 Kbit/s, UART must receive *peripheral_clock* and *module_clock* at maximum 4.3 microseconds after falling edge of Start bit). If the UART receives *peripheral_clock* and *module_clock* too late, first character will be lost, and so should be dropped. Also, if autobaud detection is enabled, the first character won't be correctly received and another autobaud detection will need to be initiated.

In Doze mode, UART behavior is programmable through DOZE bit (UCR1[1]). If DOZE bit is set to '1', then UART is disabled in Doze mode, and in consequence, UART clocks can be switched-off (after being sure UART is not transmitting nor receiving). On the contrary, if DOZE bit is set to '0', UART is enabled and it must receive *peripheral_clock* and *module_clock*.

56.4.3 General UART Definitions

Definitions of terms that occurs the following discussions are given in this section.

- Bit Time-The period of time required to serially transmit or receive 1 bit of data (1 cycle of the baud rate frequency).
- Start bit-The bit time of a logic 0 that indicates the beginning of a data frame. A start bit begins with a 1-to-0 transition, and is preceded by at least 1 bit time of logic 1.
- Stop bit-1 bit time of logic 1 that indicates the end of a data frame.
- BREAK-A frame in which all of the data bits, including the stop bit, are logic 0. This type of frame is usually sent to signal the end of a message or the beginning of a new message.
- Mark - When no data is being sent, the serial port's transmit pin's voltage is 1 and is said to be in a MARK state.
- Space - The serial port can also be forced to keep the transmit pin at a 0 and is said to be the SPACE or BREAK state.
- Frame-A start bit followed by a specified number of data or information bits and terminated by a stop bit. The number of data or information bits depends on the

format specified and must be the same for the transmitting device and the receiving device. The most common frame format is 1 start bit followed by 8 data bits (least significant bit first) and terminated by 1 stop bit. An additional stop bit and a parity bit also can be included.

- **Framing Error**-An error condition that occurs when the stop bit of a received frame is missing, usually when the frame boundaries in the received bit stream are not synchronized with the receiver bit counter. Framing errors can go undetected if a data bit in the expected stop bit time happens to be a logic 1. A framing error is always present on the receiver side when the transmitter is sending BREAKs. However, when the UART is programmed to expect 2 stop bits and only the first stop bit is received, this is not a framing error by definition.
- **Parity Error**-An error condition that occurs when the calculated parity of the received data bits in a frame does not match the parity bit received on the RX_DATA input. Parity error is calculated only after an entire frame is received.
- **Idle**-One in NRZ encoding format and selectable polarity in IrDA mode.
- **Overrun Error**-An error condition that occurs when the latest character received is ignored to prevent overwriting a character already present in the UART receive buffer (RxFIFO). An overrun error indicates that the software reading the buffer (RxFIFO) is not keeping up with the actual reception of characters on the RX_DATA input.

56.4.3.1 RTS_B - UART Request To Send

The UART Request To Send input controls the transmitter. The modem or other terminal equipment signals the UART when it is ready to receive by setting '0' on the RTS_B pin.

Normally, the transmitter waits until this signal is active (low) before transmitting a character, however when the Ignore RTS (IRTS) bit is set, the transmitter sends a character as soon as it is ready to transmit. An interrupt (RTSD) can be posted on any transition of this pin and can wake the ARM platform from STOP mode on its assertion. When RTS_B is set to '1' during a transmission, the UART transmitter finishes transmitting the current character and shuts off. The contents of the TxFIFO (characters to be transmitted) remain undisturbed. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode.

56.4.3.2 RTS Edge Triggered Interrupt

The input to the RTS_B pin can be programmed to generate an interrupt on a selectable edge.

See the table below for summary of the operation of the RTS edge triggered interrupt (RTSF).

To enable the RTS_B pin to generate an interrupt, set the request to send interrupt enable (RTSEN) bit (UCR2[4]) to 1. Writing 1 to the RTS_B edge triggered interrupt flag (RTSF) bit (USR2[4]) clears the interrupt flag. The interrupt can occur on the rising edge, falling edge, or either edge of the RTS_B input. The request to send edge control (RTEC) field (UCR2[10:9]) programs the edge that generates the interrupt. When RTEC is set to 0x00 and RTSEN = 1, the interrupt occurs on the rising edge (default). When RTEC is set to 0x01 and RTSEN = 1, the interrupt occurs on the falling edge. When RTEC is set to 0x1X and RTSEN = 1, the interrupt occurs on either edge. This is a synchronous interrupt. The RTSF bit is cleared by writing 1 to it. Writing 0 to RTSF has no effect.

Table 56-5. RTS_B Edge Triggered Interrupt Truth Table

RTS_B	RTSEN	RTEC [1]	RTEC [0]	RTSF	Interrupt Occurs On...	interrupt_uart
X	0	X	X	0	Interrupt disabled	1
1->0	1	0	0	0	Rising edge	1
0->1	1	0	0	1	Rising edge	0
1->0	1	0	1	1	Falling edge	0
0->1	1	0	1	0	Falling edge	1
1->0	1	1	X	1	Either edge	0
0->1	1	1	X	1	Either edge	0

There is another RTS_B interrupt that is not programmable. The status bit RTSD asserts the *interrupt_uart* interrupt when the RTS_B delta interrupt enable = 1. This is an asynchronous interrupt. The RTSD bit is cleared by writing 1 to it. Writing 0 to the RTSD bit has no effect.

56.4.3.3 DTR_B - Data Terminal Ready

This signal indicates the general readiness of the Data Terminal Equipment (DTE). This signal is an input in DCE mode and an output in DTE mode. If the connection between the DCE and the DTE is established once, the DTR_B signal must remain active throughout the whole connection time.

In general the DTR_B and DSR_B signals are responsible for establishing the connection. RTS_B and CTS_B are responsible for the data transfer and the transfer direction in the case of a half-duplex configuration. The DTR_B signal is like a "main switch". If the DTR_B signal is inactive the RTS_B and CTS_B signals have no effect. In DCE mode, an interrupt (DTRD) can be posted on any transition of this pin and can wake the ARM platform from STOP mode on its assertion.

56.4.3.4 DSR_B - Data Set Ready

This signal indicates the general readiness of the DCE. This signal is an output in DCE mode and an input in DTE mode. The DCE uses this signal to inform the DTE that it is switched on, has completed all preparations and can communicate with the DTE.

In DTE mode, an interrupt (DTRD) can be posted on any transition of this pin and can wake the ARM platform from STOP mode on its assertion.

56.4.3.5 DTR_B/DSR_B Edge Triggered Interrupt

The DTR_B input pin (DCE mode) or DSR_B input pin (DTE mode) can be configured to cause an interrupt on a selectable edge.

See the table below for summary of the operation of the DTR/DSR edge triggered interrupt. To enable the interrupt, set the DTREN bit (UCR3[13]) to '1'. Write a "one" to the DTRF bit (USR2[13]) to clear the interrupt flag.

The interrupt can be configured to occur on either the rising, falling, or either edge of the DTR_B/DSR_B input. Write to the DPEC[1:0] bits (UCR3[15:14]) to program which edge will cause an interrupt. If the bits are set to 00b and DTREN = 1, the interrupt will occur on the rising edge (default). If the bits are set to 01b and DTREN = 1, the interrupt will occur on the falling edge. If the bits are set to 1Xb and DTREN = 1, the interrupt will occur on either edge.

Table 56-6. DTR/DSR_B Edge Triggered Interrupt Truth Table

DTR_B / DSR_B	DTREN	DPEC[1]	DPEC[0]	DTRF	Interrupt occurs on:	interrupt_uart
X	0	X	X	0	turned off	1
1->0	1	0	0	0	rising edge	1
0->1	1	0	0	1	rising edge	0
1->0	1	0	1	1	falling edge	0
0->1	1	0	1	0	falling edge	1
1->0	1	1	X	1	either edge	0
0->1	1	1	X	1	either edge	0

56.4.3.6 DCD_B - Data Carrier Detect

This signal is an output in DCE mode and an input in DTE mode. If used, the DCE device uses this signal to inform the DTE it has detected the carrier signal and the connection will be set up. This signal remains active while the connection remains established.

In DTE mode this input can trigger an interrupt on changing state. This is achieved by setting to '1' the interrupt enable bit (DCD, UCR3[9]). The change state is reflected in DCDELTA (USR2[6]). Also, the state of the Data Carrier Detect input is mirrored in the status register DCDIN (USR2[5]).

56.4.3.7 RI_B - Ring Indicator

This signal is an output in DCE mode and an input in DTE mode. If used, the DCE device uses this signal to inform the DTE that a ring just occurred.

In DTE mode this input can trigger an interrupt on changing state. This is achieved by setting to '1' the interrupt enable bit (RI, UCR3[8]). The change state is reflected in RIDELTA (USR2[10]). Also, the state of the Ring Indicator input is mirrored in the status register RIIN (USR2[9]).

56.4.3.8 CTS_B - Clear To Send

This output pin serves two purposes. Normally, the receiver indicates that it is ready to receive data by asserting this pin (low). When the CTS_B trigger level is programmed to trigger at 32 characters received and the receiver detects the valid start bit of the 33 character, it de-asserts this pin. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode.

56.4.3.9 Programmable CTS_B Deassertion

The CTS_B output can also be programmed to deassert when the RxFIFO reaches a certain level. Setting the CTS trigger level (UCR4[15:10]) at any value less than 32 deasserts the CTS_B pin on detection of the valid start bit of the N + 1 character (where N is the trigger level setting). However, the receiver continues to receive characters until the RxFIFO is full.

56.4.3.10 TX_DATA - UART Transmit

This is the transmitter serial output. When operating in RS-232/RS-485 mode, NRZ encoded data is transmitted, and the data can be inverted (controlled by INVT (UCR3[1])) before transmitted. When operating in infrared mode, a 3/16 bit-period pulse is output for each 0 bit transmitted, and no pulse is output for each 1 bit transmitted.

For RS-232/RS-485 applications, this pin must be connected to an RS-232/RS-485 transmitter. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode. See [Figure 56-3](#).

56.4.3.11 RX_DATA - UART Receive

This is the receiver serial input. When operating in RS-232/RS-485 mode, NRZ encoded data is expected, and the data can be inverted (controlled by INVR (UCR4[9])) before sampled. When operating in infrared mode, a narrow pulse is expected for each 0 bit received and no pulse is expected for each 1 bit received.

External circuitry must convert the IR signal to an electrical signal. RS-232/RS-485 applications require an external RS-232/RS-485 receiver to convert voltage levels. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode. See the figure below.

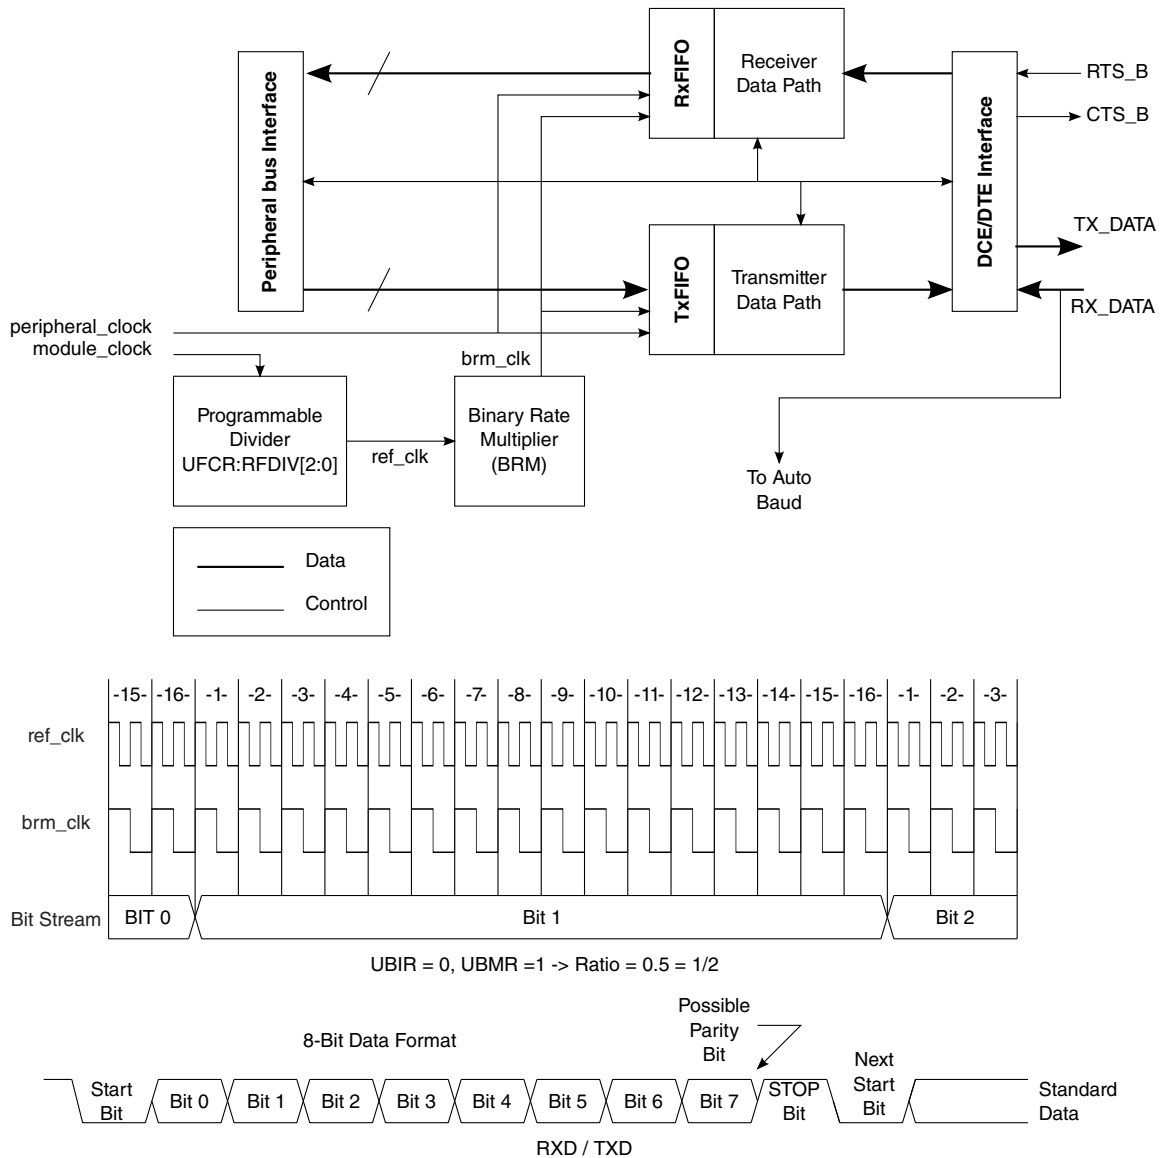

Figure 56-3. UART Simplified Block and Clock Generation Diagrams

56.4.4 Transmitter

The transmitter accepts a parallel character from the ARM platform and transmits it serially. The start, stop, and parity (when enabled) bits are added to the character.

When the ignore RTS bit (IRTS) is set, the transmitter sends a character as soon as it is ready to transmit. RTS_B can be used to provide flow-control of the serial data. When RTS_B is set to '1', the transmitter finishes sending the character in progress (if any), stops, and waits for RTS_B to be set to '0' again. Generation of BREAK characters and parity errors (for debugging purposes) is supported. The transmitter operates from the clock provided by the Binary Rate Multiplier(BRM). Normal NRZ encoded data is transmitted when the IR interface is disabled.

The transmitter FIFO (TxFIFO) contains 32 bytes. The data is written to TxFIFO by writing to the UTXD register with the byte data to the [7:0] bits. The data is written consecutively if the TxFIFO is not full. It is read (internally) consecutively if the TxFIFO is not empty. TXFULL bit (UTS[4]) can be used to control whether TxFIFO is full or not. The TxFIFO can be written regardless of the transmitter is disabled or enabled. If the UART is disabled, user can still write data into the TxFIFO correctly. But in this case the write access will yield to a transfer error.

56.4.4.1 Transmitter FIFO Empty Interrupt Suppression

The transmitter FIFO empty interrupt suppression logic suppresses the TXFE interrupt between writes to the TxFIFO.

When TxFIFO is empty, the software can either send one or several characters. If the software sends one character, it would write the character into the UTXD register, then that character is immediately transferred to the transmitter shift register, assuming the transmitter is already enabled. Without interrupt suppression logic, the TXFE interrupt flag would be set immediately. But, with this logic, the interrupt flag is set when the last bit of the character has been transmitted, for example, before the transmission of the parity bit (if exists) and the stop bit(s).

So, the suppression logic doesn't immediately send the TXFE interrupt flag. It allows the software to write another character to the TxFIFO before the interrupt flag is asserted.

When the transmitter shift register empties before another character is written to the TxFIFO, the interrupt flag is asserted. Writing data to the TxFIFO would release the interrupt flag. The interrupt flag is asserted on the following conditions:

- System Reset

Functional Description

- UART software reset
- When a single character has been written to Transmitter FIFO and then the Transmitter FIFO and the Transmitter Shift Register become empty until another character is written to the Transmitter FIFO
- The last character in the TxFIFO is transferred to the shift register, when TxFIFO contains two or more characters. See the figure below.

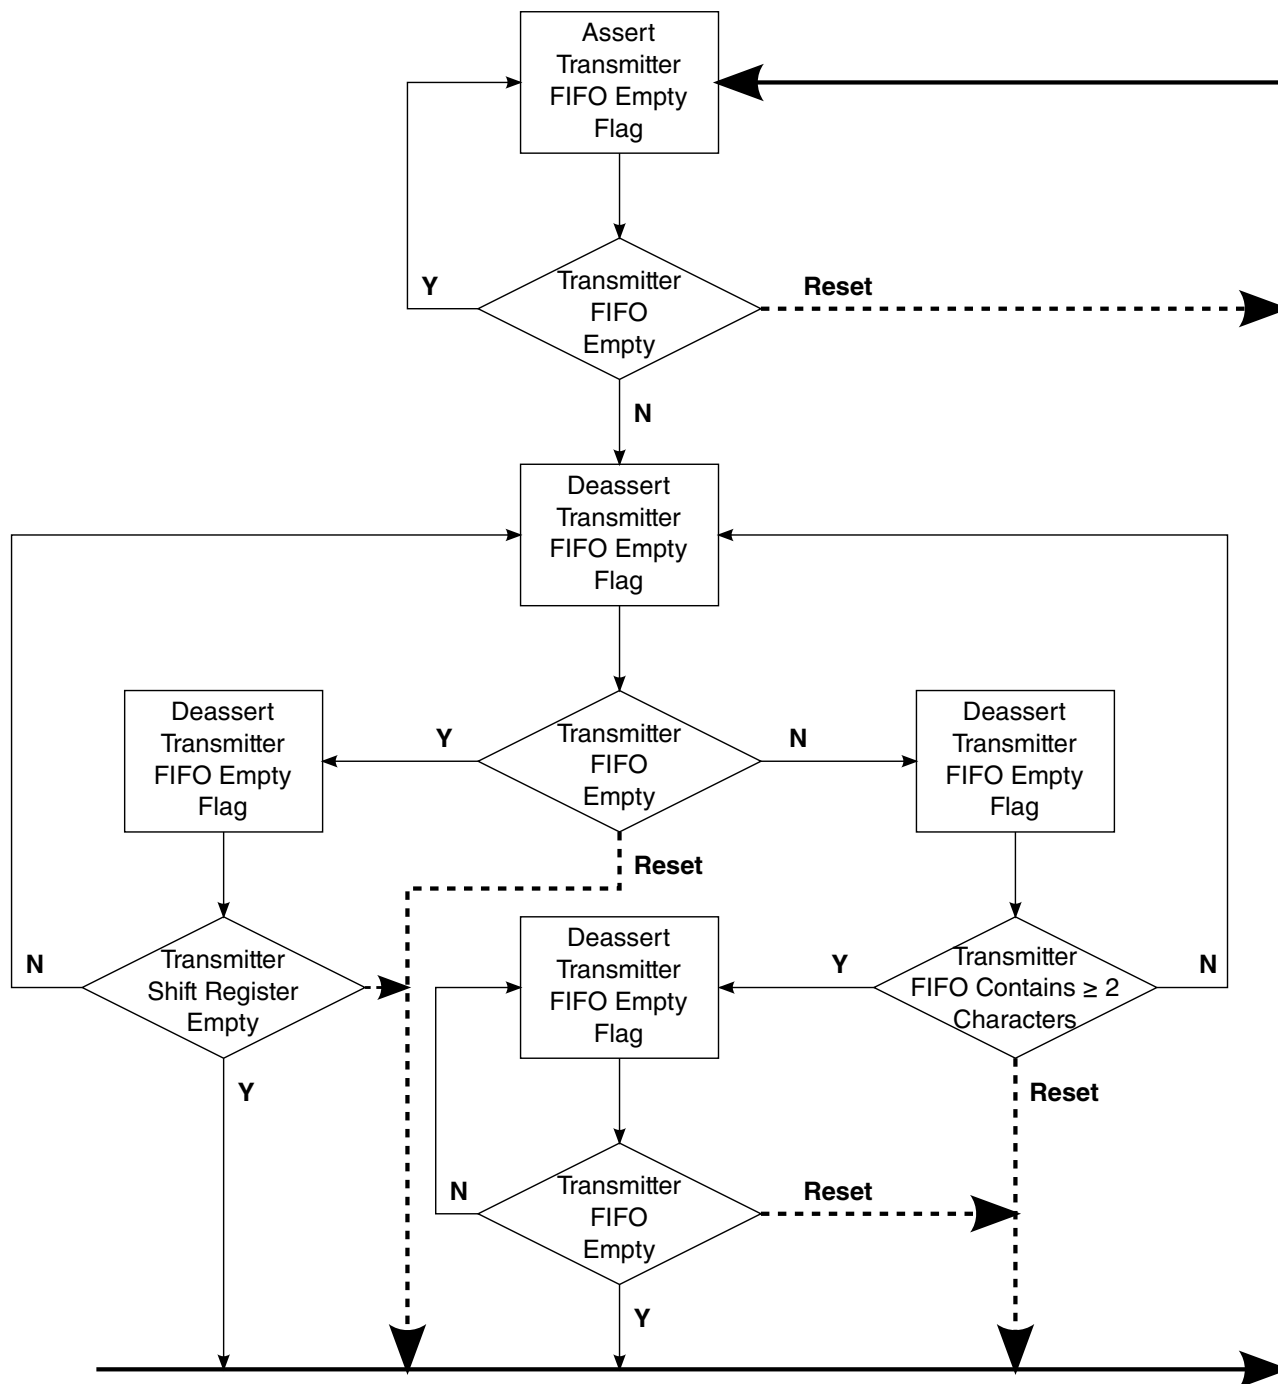

Figure 56-4. Transmitter FIFO Empty Interrupt Suppression Flow Chart

56.4.4.2 Transmitting a Break Condition

Asserting SNDBRK bit of the UCR1 Register forces the transmitter to send a break character (continuous zeros). The transmitter will finish sending the character in progress (if any) before sending break until this bit is reset.

The user is responsible to ensure that this bit is high for long enough to generate a valid BREAK. The transmitter samples SNDBRK after every bit is transmitted. Following completion of the BREAK transmission, the UART will transmit two mark bits. The user can continue to fill the FIFO and any character remaining will be transmitted when the break is terminated.

56.4.5 Receiver

See the figure below for the receiver flow chart.

The receiver accepts a serial data stream and converts it into parallel characters. When enabled, it searches for a start bit, qualifies it, and samples the following data bits at the bit-center.

Jitter tolerance and noise immunity are provided by sampling at a 16x rate and using voting techniques to clean up the samples. Once the start bit is found, the data bits, parity bit (if enabled), and stop bits (either 1 or 2 depending on user selection) are shifted in. Parity is checked and its status reported in the URXD register when parity is enabled. Frame errors and BREAKs are also checked and reported. When a new character is ready to be read by the ARM platform from the RxFIFO, the receive data ready (RDR = $USR2[0]$) bit is asserted and an interrupt is posted (if $DREN = UCR4[0] = 1$). If the receiver trigger level is set to 2 ($RXTL[5:0] = UFCR[5:0] = 2$), and 2 chars have been received into RxFIFO, the receiver ready interrupt flag ($RRDY = USR1[9]$) is asserted and an interrupt is posted if the receiver ready interrupt enable bit is set ($RRDYEN = UCR1[9] = 1$). If the UART Receiver Register (URXD) is read once, and in consequence there is only 1 character in the RxFIFO, the interrupt generated by the RDR bit is automatically cleared. The RRDY bit is cleared when the data in the RxFIFO falls below the programmed trigger level.

Normal NRZ encoded data is expected when the IR interface is disabled. The RxFIFO contains 32 half-word entries. Characters received are written consecutively into this FIFO. If the FIFO is full and a 33rd character is received, this character will be ignored and the $USR2[ORE]$ bit will be set.

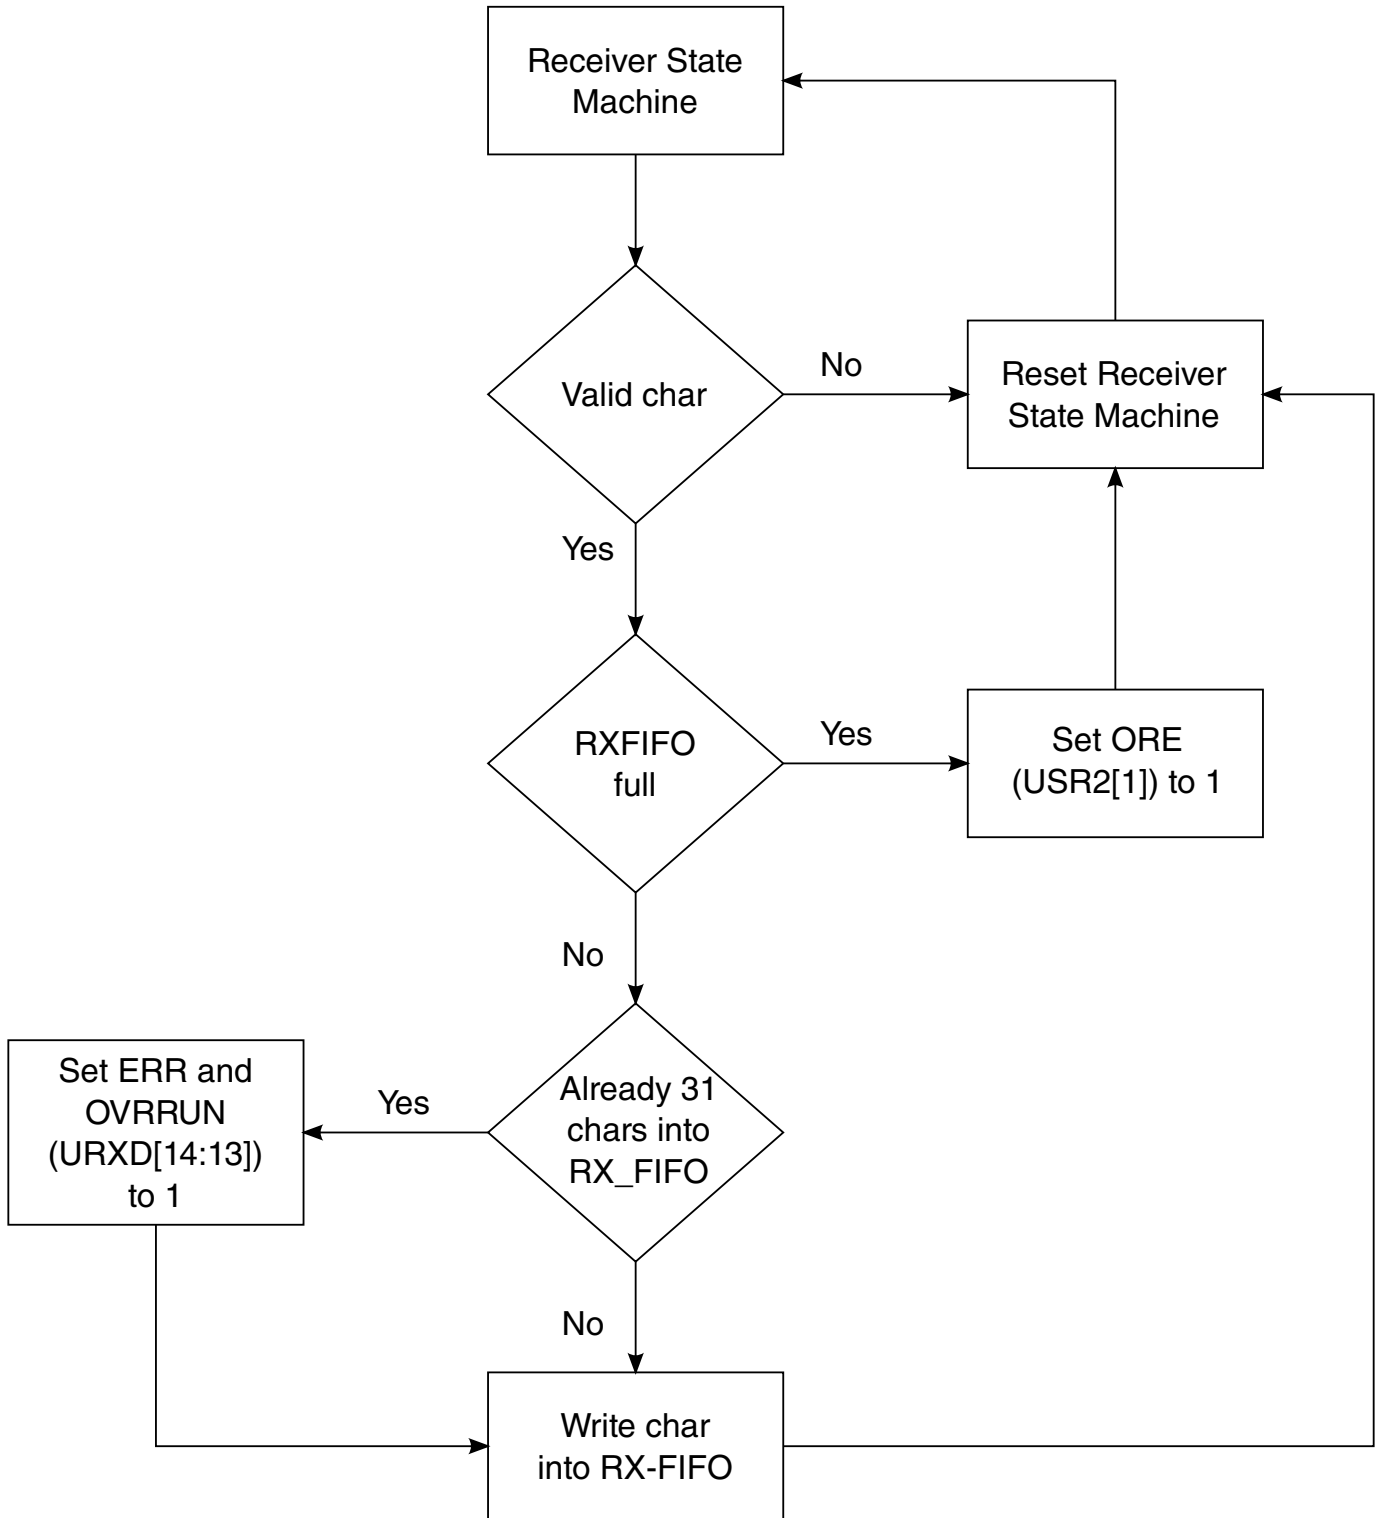

Figure 56-5. Receiver Flow Chart

56.4.5.1 Idle Line Detect

The receiver logic block includes the ability to detect an idle line. Idle lines indicate the end or the beginning of a message.

For an idle condition to occur:

- RxFIFO must be empty and
- RX_DATA pin must be idle for more than a configured number of frames (ICD[1:0] = UCR1[11:10]).

When the idle condition detected interrupt enable (IDEN = UCR1[12]) is set and the line is idle for 4 (default), 8, 16, or 32 (maximum) frames, the detection of an idle condition flags an interrupt (see the table below). When an idle condition is detected, the IDLE (USR2[12]) bit is set. Clear the IDLE bit by writing 1 to it. Writing 0 to the IDLE bit has no effect.

Table 56-7. Detection Truth Table

IDEN	ICD [1]	ICD [0]	IDLE	<i>interrupt_uart</i>
0	X	X	0	1
1	0	0	asserted after 4 idle frames	asserted after 4 idle frames
1	0	1	asserted after 8 idle frames	asserted after 8 idle frames
1	1	0	asserted after 16 idle frames	asserted after 16 idle frames
1	1	1	asserted after 32 idle frames	asserted after 32 idle frames

NOTE: This table assumes that no other interrupt is set at the same time this interrupt is set for the *interrupt_uart* signal. This table shows how this interrupt affects the *interrupt_uart* signal.

During a normal message there is no idle time between frames. When all of the information bits in a frame are logic 1s, the start bit ensures that at least one logic 0 bit time occurs for each frame so that the IDLE bit is not asserted.

56.4.5.2 Aging Character Detect

The receiver block also includes the possibility to detect when at least one character has been sitting into the RxFIFO for a time corresponding to 8 characters. This aging character capability allows the UART to inform the ARM platform that there is less character into the RxFIFO than the Rx trigger and, no new character has been detected on the RXD line.

The aging capability is a timer which starts to count as soon as the RxFIFO is not empty and its trigger level is not reached (RRDY=0). This counter is reset when either a RxFIFO read is performed or another character starts to present on the RXD line. If none of those two events occurs, the bit AGTIM (USR1[8]) is set when the counter has

measured a time corresponding to 8 characters. AGTIM is cleared by writing a 1 to it. AGTIM can flag an interrupt to ARM platform on *interrupt_uart* if ATEN (UCR2[3]) has been set.

To summarize, AGTIM is set when:

- There is at least one character into RxFIFO.
- No read has occurred on RxFIFO and RXD line has stayed high, for a time corresponding to 8 characters.
- The RxFIFO trigger is not reached (RRDY=0)

56.4.5.3 Receiver Wake

The WAKE bit (USR2[7]) is set when the receiver detects a qualified Start bit. For this, two conditions must be fulfilled, firstly a falling edge on RX_DATA line must be detected and secondly the RX_DATA line must stay at low level for more than a half-bit duration.

When the wake interrupt enable WKEN (UCR4[7]) bit is enabled, the receiver flags an interrupt (*interrupt_uart*) if the WAKE status bit is set. The WAKE bit is cleared by writing 1 to it. Writing 0 to the WAKE bit has no effect. The WAKE status bit can be asserted in either serial RS-232 mode or IR mode. The generation of the WAKE interrupt needs the clock *module_clock*.

When the asynchronous wake interrupt (AWAKE) is enabled (AWAKEN = UCR3[4] = 1), and the ARM platform is in STOP mode, and UART clocks have been shut-off, then a falling edge detected on the receive pin (RX_DATA) asserts the AWAKE bit (USR1[4]) and the *interrupt_uart* interrupt to wake the ARM platform from STOP mode. Re-enable UART clocks and clear the AWAKE bit by writing 1 to it. Writing 0 to the AWAKE bit has no effect. When IR interface is enabled (UCR1[7]=1), the AWAKE bit is always not asserted. The generation of the asynchronous AWAKE interrupt does not need any clocks.

In IR mode, if the asynchronous IR WAKE interrupt is enabled (AIRINTEN = UCR3[5] = 1), and if the ARM platform is in STOP mode (UART clocks are off when ARM platform in STOP mode), then the detection of a falling edge on the receive pin (RXD_IR), asserts the AIRINT bit (USR1[5]), and the *interrupt_uart* interrupt. This interrupt wakes the ARM platform from STOP mode. Software re-enables UART clocks and clear the AIRINT bit by writing 1 to it. Writing 0 to the AIRINT bit has no effect. When IR interface is disabled (UCR1[7]=0), the AIRINT bit is always not asserted. The generation of the asynchronous AIRINT interrupt does not need any clocks.

Recommended procedure for programming the asynchronous interrupts is to first clear them by writing 1 to the appropriate bit in the UART Status Register 1 (USR1). Poll or enable the interrupt for the Receiver IDLE Interrupt Flag (RXDS) in the USR1. When asserted, the RXDS bit indicates to the software that the receiver state machine is in the idle state, the next state is idle, and the RX_DATA pin is idle (high). After following this procedure, enable the asynchronous interrupt and enter STOP mode.

56.4.5.4 Receiving a BREAK Condition

A BREAK condition is received when the receiver detects all 0s (including a 0 during the bit time of the stop bit) in a frame. The BREAK condition asserts the BRCD bit (USR2[2]) and writes only the first BREAK character to the RxFIFO. Clear the BRCD bit by writing 1 to it. Writing 0 to the BRCD bit has no effect.

Asserting BRCD would generate an interrupt on *interrupt_uart*. The interrupt generation can be masked using the control bit BKEN (UCR4[2]). Receiving a break condition will also effect the following bits in the receiver register URXD:

URXD(11) = BRK. While high this bit indicates that the current char was detected as a break.

URXD(12) = FRMERR. The frame error bit will always be set when BRK is set.

URXD(10) = PRERR. If odd parity was selected the parity error bit will also be set when BRK is set.

URXD(14) = ERR. The error detect bit indicates that the character present in the rx data field has an error status. This can be asserted by a break.

56.4.5.5 Vote Logic

The vote logic block provides jitter tolerance and noise immunity by sampling with respect to a 16x clock (*brm_clk*) and using voting techniques to clean up the samples. The voting is implemented by sampling the incoming signal constantly on the rising edge of the *brm_clk*.

See [Figure 56-6](#). The receiver is provided with the majority vote value, which is 2 out of the 3 samples. For examples of the majority vote results of the vote logic, see the following table.

Table 56-8. Majority Vote Results

Samples	Vote
000	0
101	1
001	0
111	1

The vote logic captures a sample on every rising edge of *brm_clk*, however the receiver uses 16x oversampling to take its value in the middle of the sample character.

The receiver starts to count when the Start bit is set however it does not capture the contents of the RxFIFO at the time the Start bit is set. The start bit is validated when 0s are received for 7 consecutive 1/16 of bit times following the 1-to-0 transition. Once the counter reaches 0xF, it starts counting on the next bit and captures it in the middle of the sampling frame (see [Table 56-8](#)). All data bits are captured in the same manner. Once the stop bit is detected, the receiver shift register (SIPO_OUT) data is parallel shifted to the RxFIFO.

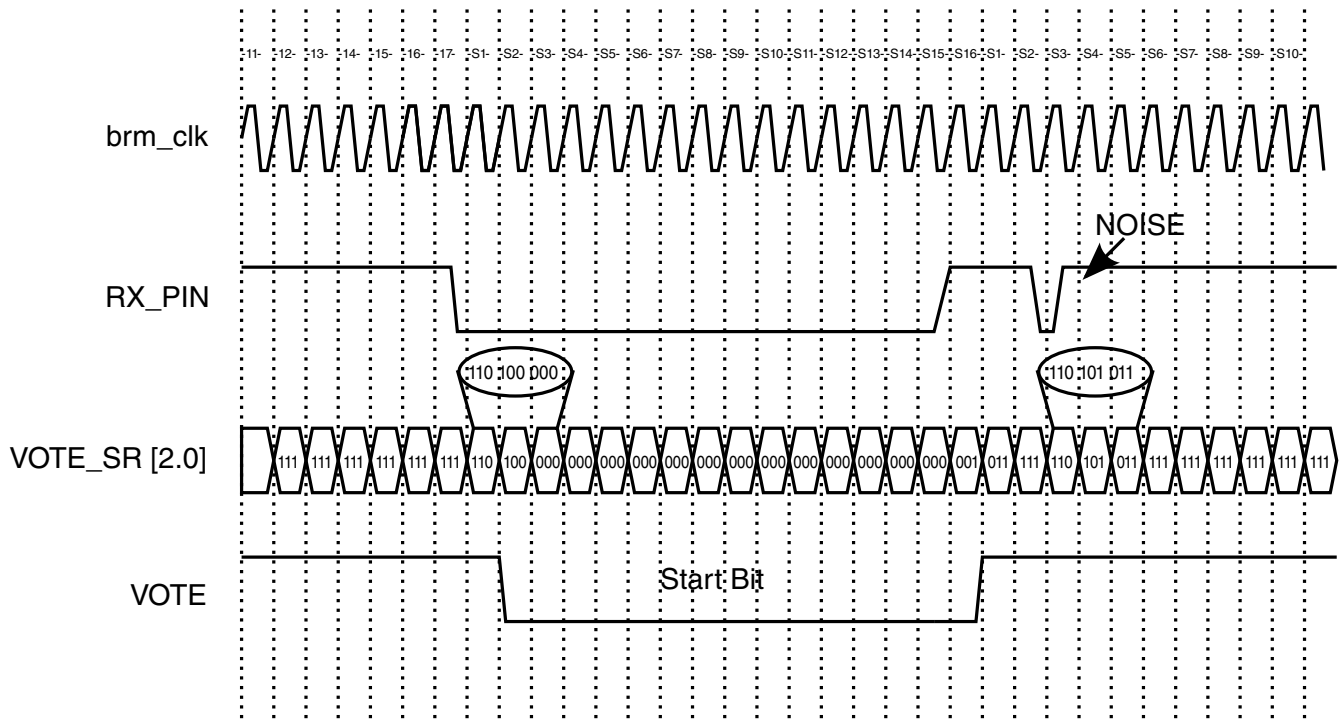

Figure 56-6. Majority Vote Results

A new feature has been recently implemented, it allows to re-synchronize the counter on each edge of RX_DATA line. This is automatic and allows to improve the immunity of UART against signal distortion.

There is a special case when the *brm_clk* frequency is too low and is unable to capture a 0 pulse in IrDA. In this case, the software must set the IRSC (UCR4[5]) bit so that the reference clock (after internal divider) is used for the voting logic. The pulse is validated by counting the length of the pulse.

Refer to [Infrared Interface](#) for more details.

56.4.5.6 Baud Rate Automatic Detection Logic

When the baud rate automatic detection logic is enabled, the UART locks onto the incoming baud rate. To enable this feature, set the automatic detection of baud rate bit (ADBR = UCR1[14] = 1) and write 1 to the ADET bit (USR2[15]) to clear it.

When ADET=0 and ADBR =1, the detection starts. Then, once the beginning of start bit (transition from 1-to-0 of RX_DATA) has been detected, UART starts a counter (UBRC) working at reference frequency. Once the end of start bit is detected (transition from 0-to-1 of RX_DATA), the value of UBRC - 1 is directly copied into UBMR register. UBIR register is filled with 0x000F.

So, at the end of start bit, registers gets following values:

```
UBRC = number of reference clock periods (after divider) during Start bit.
UBIR = 0x000F
UBMR = UBRC - 1
```

The updated values of the 3 registers can be read.

See [Table 56-9](#) for list of parameters for baud rate detection and [Figure 56-7](#) for baud rate detection protocol diagram.

If any of the UART BRM registers are simultaneously written by the baud rate automatic detection logic and by the peripheral data bus, the peripheral data bus would have lower priority.

Table 56-9. Baud Rate Automatic Detection

ADBR	ADET	Baud Rate Detection	<i>interrupt_uart</i>
0	X	Manual Configuration	1
1	0	Auto Detection Started	1
1	1	Auto Detection Complete	0

NOTE: This table assumes that no other interrupt is set at the same time this interrupt is set for the *interrupt_uart* signal.

Note: LSB Transmitted first.

Figure 56-7. Baud Rate Detection Protocol Diagram

56.4.5.6.1 Baud Rate Automatic Detection Protocol

The receiver must receive an ASCII character "A" or "a" to verify proper detection of the incoming baud rate. When an ASCII character "A" (0x41) or "a" (0x61) is received and no error occurs, the Automatic Detect baud rate bit is set (ADET=1) and if the interrupt is enabled (ADEN=UCR1[15]=1), an interrupt *interrupt_uart* is generated.

When an ASCII character "A" or "a" is not received (because of a bit error or the reception of another character), the auto detection sequence restarts and waits for another 1-to-0 transition.

As long as ADET = 0 and ADBR = 1, the UART continues to try to lock onto the incoming baud rate. Once the ASCII character "A" or "a" is detected and the ADET bit is set, the receiver ignores the ADBR bit and continues normal operation with the calculated baud rate.

The UART interrupt is active (*interrupt_uart* = 0) as long as ADET = 1 and ADBR = 1. This can be disabled by clearing the automatic baud rate detection interrupt enable bit (ADEN = 0). Before starting an automatic baud rate detection sequence, set ADET = 0 and ADBR = 1.

The RxFIFO must contain the ASCII character "A" or "a" following the automatic baud rate detection interrupt.

The 16-bit UART Baud Rate Count Register (UBRC) is reset to 4 and stays at 0xFFFF when an overflow occurs. The UBRC register counts (measures) the duration of start bit. When the start bit is detected and counted, the UART Baud Rate Count Register retains its value until the next automatic baud rate detection sequence is initiated.

The Baud Rate Count Register counts only when auto detection is enabled.

56.4.5.6.2 New Baud Rate Determination

In order to fight against the problems caused by the distortion and the noise on the RX_DATA line, the duration of the baud rate measurement has been extended.

Previously, as described above, this determination was based on the measurement of the START bit duration. Now, this measurement is based on the duration of START bit + bit0. Bit0 is the first bit following the START bit. In fact, the counter which is started at the falling edge of START bit is no longer stopped at next rising edge (end of START bit), but it is stopped at the next falling edge (end of bit0). As the character sent is always a "A" (41h) or a "a" (61h), this second falling edge will always be present and it will indicate the end of bit0. Once this counter is stopped, the result is divided by 2 and used by the BRM to determine the incoming baud rate.

NOTE

UBRC register contains the result of this division by two, in consequence it reflects the measurement of the duration of one bit.

56.4.5.6.2.1 New Autobaud Counter Stopped bit and Interrupt

A new bit has been added in USR2 register: ACST (USR2[11]). This bit is set immediately after the determination of the baud rate.

So,

- if ADNIMP is not set (default), ACST is set to 1 after the end of bit0,
- If ADNIMP is set to 1, ACST is set to 1 at the end of START bit.

If ACIEN (UCR3[0]) is set to 1, ACST will flag an interrupt on *interrupt_uart* signal. This interrupt informs the ARM platform that the BRM has just been set with the result of the bit length measurement. If needed, the ARM platform can perform a read of UBMR (or UBRC) register and determine by itself the baud rate measured. Then the ARM platform has the possibility to correct the BRM registers with the nearest standardized baud rate.

NOTE

ACST is set only if ADBR is set to 1, for example, the UART is autobauding.

Clear the ACST bit by writing 1 to it. Writing 0 to the ACST bit has no effect.

56.4.6 Escape Sequence Detection

An escape sequence typically consists of 3 characters entered in rapid succession (such as +++). Because these are valid characters by themselves, the time between characters determines if it is a valid escape sequence.

Too much time between two of the "+" characters is interpreted as two "+" characters, and not part of an escape sequence.

The software chooses the escape character and writes its value to the UART Escape Character Register (UESC). The software must also enable escape detection feature by setting ESCEN (UCR2[11]) to 1. The hardware compares this value to incoming characters in the RxFIFO. When an escape character is detected, the internal escape timer starts to count. The software specifies a time-out value for the maximum allowable time between 2 successive escape characters (see the table below). The escape timer is programmable in intervals of 2 ms to a maximum interval of 8.192 seconds.

Table 56-10. Escape Timer Scaling

UTIM Register	Maximum Time Between Specified Escape Characters
0x000	2 ms
0x001	4 ms
0x002	6 ms
0x003	8 ms
0x004	10 ms
...	...
0F8	498 ms
0F9	500 ms
...	...
9C3	5 s
...	...
FFD	8.188 s
FFE	8.190 s
FFF	8.192 s
<p>NOTE: To calculate the time interval: $(\text{UTIM_Value} + 1) \times 0.002 = \text{Time_Interval}$ Example: $(09C3 + 1) \times 0.002 = 5 \text{ s.}$</p>	

The escape sequence detection feature is available for all the reference frequencies. Before using Escape Sequence Detection, the user must fill the ONEMS register. This 24-bit register must contain the value of the UART internal frequency divided by 1000. The internal frequency is obtained after the UART internal divider which is applied on *module_clock* clock.

Example I:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 2 with the internal divider:
UFCR[9:7] = 3'b100

$$\text{ONEMS} = \frac{66.5 \times 10^6}{2 \times 1000} = 33250 = 81E2\text{h}$$

Figure 56-8. Calculation of Frequency for ONEMS Register

Example II:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 1 with the internal divider:
UFCR[9:7] = 3'b101

$$\text{ONEMS} = \frac{66.5 \times 10^6}{1000} = 66500 = 103C4\text{h}$$

Figure 56-9. Calculation of Frequency for ONEMS Register

The escape sequence detection interrupt is asserted when the escape sequence interrupt enable (ESCI) bit is set and an escape sequence is detected (ESCF set). Clear the ESCF bit by writing 1 to it. Writing 0 to the ESCF bit has no effect.

56.5 Binary Rate Multiplier (BRM)

The BRM sub-block receives *ref_clk* (*module_clock* clock after divider). From this clock, and with integer and non-integer division, BRM generates a 16x baud rate clock .

Binary Rate Multiplier (BRM)

The UART transmitter will shift data out based on this 16x baud rate clock. The UART receiver will sample the serial data line based on this 16x baud rate clock. The input and output frequency ratio is programmed in the UART BRM Incremental Register (UBIR) and UART BRM MOD Register (UBMR). The output frequency is divided by the input frequency to produce this ratio. For integer division, set the UBIR = 0x000F and write the divisor to the UBMR register. All values written to these registers must be one less than the actual value to eliminate division by 0 (undefined), and to increase the maximum range of the registers.

Updating the BRM registers requires writing to both registers. The UBIR register must be written before writing to the UBMR register. If only one register is written to by the software, the BRM continues to use the previous values.

The following examples show how to determine what values are to be programmed into UBIR and UBMR for a given reference frequency and desired baud rate. The following equation can be used to help determine these values:

$$\text{BaudRate} = \frac{\text{Ref Freq}}{\left(16 \times \frac{\text{UBMR} + 1}{\text{UBIR} + 1} \right)}$$

Figure 56-10. Frequency and Baud Rate for UBIR and UBMR

With:

Reference Frequency (Hz): UART Reference Frequency (*module_clock* after RFDIV divider)

Baud Rate (bit/s): Desired baud rate.

Integer Division ÷ 21

Reference Frequency = 19.44 MHz

UBIR = 0x000F

UBMR = 0x0014

Baud Rate = 925.7 kbit/s

NOTE

Observe that each value written to the registers is one less than the actual value.

Non-Integer Division

Reference Frequency = 16 MHz
 Desired Baud Rate = 920 Kbits/s

$$\frac{UBMR + 1}{UBIR + 1} = \frac{\text{RefFreq}}{16 \times \text{BaudRate}} = \frac{16 \times 10^6}{16 \times 920 \times 10^3} = 1.087$$

Ratio = 1.087 = 1087 / 1000
 UBIR = 999 (decimal) = 0x3E7
 UBMR = 1086 (decimal) = 0x43E
 Non-Integer Division
 Reference Frequency = 25 MHz
 Desired Baud Rate = 920 kbit/s
 Ratio = 1.69837 = 625 / 368
 UBIR = 367 (decimal) = 0x16F
 UBMR = 624 (decimal) = 0x270

Non-Integer Division

Reference Frequency: 30 MHz
 Desired Baud Rate = 115.2 kbit/s
 Ratio = 16.276043 = 65153 / 4003
 UBIR = 4002 (decimal) = 0x0FA2
 UBMR = 65152 (decimal) = 0xFE80

56.6 Infrared Interface

56.6.1 Generalities-Infrared

The Infrared interface is selected when IREN (UCR1[7]) is set to 1.

The Infrared Interface is compatible with IrDA Serial Infrared Physical Layer Specification. In this specification, a "zero" is represented by a positive pulse, and a "one" is represented by no pulse (line remains low).

In the UART:

In TX: For each "zero" to be transmitted, a narrow positive pulse which is 3/16 of a bit time is generated. For each "one" to be transmitted no pulse is generated (output is low). External circuitry has to be provided to drive an Infrared LED.

In RX: When receiving, a narrow negative pulse is expected for each "zero" transmitted while no pulse is expected for each "one" transmitted (input is high).

NOTE

Rx part of IR block expects to receive an inverted signal compared to IrDA specification. Circuitry external to the IC transforms the Infrared signal to an electrical signal.

The IR interface has an edge triggered interrupt (IRINT). This interrupt validates a zero bit being received. This interrupt is enabled by writing a "one" to ENIRI bit.

The behavior of Infrared Interface is determined by 3 bits INVT (UCR3[1]), INVR (UCR4[9]) and IRSC (UCR4[5]).

56.6.2 Inverted Transmission and Reception bits (INVT & INVR)

The values of INVT and INVR depend of the IrDA transceiver connected on the TXD_IR and RXD_IR pins of the UART. If this transceiver is not inverting on both paths Tx and Rx, a Zero is represented by a positive pulse and a One is represented by no pulse (line remains low). In this case, the bit INVT must be set to 0 and the bit INVR must be set to 1 (because Rx IR block expects an inverted signal).

On the contrary user must set INVT=1 and INVR=0 if both paths of the transceiver are inverting, that is, a Zero is represented as a negative pulse and a One is represented by no pulse (line remains high). The transceiver can also be inverting on only one path (Tx or Rx), in this case INVT and INVR must be together equal to 1 or to 0, depending on which path is inverted.

56.6.3 InfraRed Special Case (IRSC) Bit

The value to apply to IRSC bit is based on 2 parameters: the baud rate and the Minimum Pulse Duration (MPD) of the transceiver.

According to IrDA Standard Specification, for SIR (Serial IR) baud rates from 2.4 Kbit/s to 115.2 Kbit/s this nominal pulse duration is equal to 3/16 of a bit duration (at the selected baud rate). But, for all the baud rates a Minimum Pulse Duration is also specified. According to IrDA Standard, a Zero is represented by a light pulse, so the IrDA transceiver can't emit a light pulse shorter than the MPD. For SIR, the MPD is constant and equal to 1.41 μ s.

But user must take into account the electrical MPD associated with the transceiver on the receiver path. Typically this value is 2.0 μ s, but for some manufacturers MPD can go down to 1.0 μ s.

In order to understand the meaning of IRSC bit, one must understand how the RX path works in IrDA mode.

When the UART is in IrDA mode, a Zero is not only detected by the state of the RXD_IR line, but also with the duration of the pulse. This pulse duration can be measured with 2 different clocks. In this case, clock is selected with the IRSC bit.

- If IRSC = 0, the clock used is the BRM clock.
- If IRSC = 1, the clock used is the UART internal clock (UART clock after the divider (RFDIV)).

In normal operation, IRSC=0. This means that at any time, the user must ensure that the frequency of BRM_clock is high enough to measure the pulse. The pulse must last at least 2 BRM clock cycles. If this condition is not fulfilled, IRSC must be set to 1.

Let's examine two examples, for a Minimum Pulse Duration equal to the MPD from the IrDA SIR specification (i.e., 1.41 μ s).

1: Calculation of BRM Clock Period (Clock Period < 1.41 μ s)

The user wants to receive IrDA data at 115.2 Kbit/s. The UBIR and UBMR registers are set in order to create the BRM_clock with a frequency of $16 \times \text{baud rate} = 16 \times 115.2\text{K} = 1.843 \text{ MHz}$. But at the same time, in order to correctly detect the pulse, the user must be sure that $2 \times \text{BRM_clock period}$ is lower than 1.41 μ s. Lets check:

$$\text{BRM_clock period} = 1/1843000 = 542 \text{ ns}$$

So $2 \times \text{BRM_clock period} = 1.09 \mu\text{s} < 1.41 \mu\text{s}$. It is fine.

2: Calculation of BRM Clock Period (Clock Period > 1.41 μ s)

This time the user wants to receive at 19.2 Kbit/s. So, the BRM_clock is set to $16 \times 19200 = 307.2 \text{ kHz}$. Let's check if $2 \times \text{BRM_clock period} < 1.41 \mu\text{s}$:

1. $\text{BRM_clock period} = 1/307200 = 3.25 \mu\text{s}$

So $2 \times \text{BRM_clock period} = 6.50 \mu\text{s} \gg 1.41 \mu\text{s}$. It doesn't work.

So, in this case, the BRM clock can't be used to measure the pulse duration and the user must select the UART internal clock by setting IRSC =1.

NOTE

Like for Escape character detection, when IR Special Case is enabled (IRSC=1), the UART must measure a duration. In order to do that, the user must fill the ONEMS register. Refer to [Escape Sequence Detection](#).

56.6.4 IrDA interrupt

Serial infrared mode (SIR) uses an edge triggered interrupt flag IRINT (USR2[8]). When INVR =0, detection of a falling edge on the RXD pin asserts the IRINT bit. When INVR=1, detection of a rising edge on the RXD pin asserts the IRINT bit. When IRINT and ENIRI bits are both asserted, the *interrupt_uart* interrupt is asserted. Clear the IRINT bit by writing 1 to it. Writing 0 to the IRINT bit has no effect.

56.6.5 Conclusion about IrDA

Before using the UART in IrDA, the baud rate limit must be calculated. This baud rate limit will inform the user if IRSC bit has to be set or not.

Let's determine this limit:

As already described, if IRSC = 0, the following condition must always be fulfilled

$$2 \times \text{BRMClockPeriod} < \text{MinPulseDuration}$$

Figure 56-11. Calculation of Baud Rate

So,

$$\text{BRMClockFrequency} > \frac{2}{\text{MPD}}$$

So, knowing BRM_clock frequency = 16 * Baud Rate, we get:

$$\text{BaudRate} > \frac{1}{8 \times \text{MinPulseDuration}}$$

So, the user needs to set IRSC = 0 when:

- If Minimum Pulse Duration = 2.5 us and Baud Rate > 50 Kbit/s.
- If Minimum Pulse Duration = 2.0 us and Baud Rate > 62.5 Kbit/s.
- If Minimum Pulse Duration = 1.41 us and Baud Rate > 88.6 Kbit/s.

NOTE

For baud rates lower than the limit, IRSC must be set to 1.

56.6.6 Programming IrDA Interface

56.6.6.1 High Speed

As an example, the following sequence can be used to program the IrDA interface in order to send and receive characters at 115.2 Kbit/s.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 115.2 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to ARM platform when 1 char is received into the Rx FIFO (RDR)

Registers values and Programming orders:

```

UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART
UTS = 0x0000
UFCR = 0x0981
TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock is 30 MHz)
RXTL[5:0] = 0x01: Default value
UBIR = 0x0202
UBMR = 0x20BE Baud rate = 115.2 kbit/s with internal clock = 30 MHz
UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
UCR2[2] = TXEN = 1: Enable Rx path
UCR2[1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset
UCR3 = 0x0000

UCR4 = 0x8201
CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)

```

The UART is ready to send a character as soon as there is a write into UTXD register. And an interrupt will be sent to ARM platform when a character is received.

56.6.6.2 Low Speed

This time, we keep the same assumptions but the speed is now 9.6 Kbit/s. So, this baud rate is below the limit (even with a Min. Pulse Duration of 2.5 us) and thus IRSC must be set to 1.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 9.6 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to ARM platform when 1 char is received into the Rx FIFO (RDR).

Registers values and Programming orders:

```

UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART
UFCR = 0x0981
UFCR[15:10] = TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock is 30 MHz)
UFCR[5:0] = RXTL[5:0] = 0x01: Default value
UBIR = 0x00FF
UBMR = 0xC354 Baud rate = 9.6 kbit/s with internal clock = 30 MHz
UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
UCR2[2] = TXEN = 1: Enable Rx path
UCR2 [1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset
UCR3 = 0x0000
UCR3[1] = INVT = 0: Positive pulse represents 0.
UCR4 = 0x8221
UCR4[15:10] = CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
UCR4[5] = IRSC = 1: Because data rate is below the limit and thus the UART internal clock is
used to measure the pulse duration.
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)

```

The UART is now ready to send a character as soon as there is a write into UTXD register. An interrupt will be sent to ARM platform when a character is received.

56.7 9-bit RS-485 Mode

56.7.1 Generalities

The UART provides a 9-bit mode to facilitate multidrop (RS-485) network communication. To enable this mode, set MDEN bit in the UMCR register to 1. When 9-bit RS-485 mode is enabled, UART transmitter can transmit the ninth bit (9th bit) set by TXB8, and UART receiver can differentiate between data frames (9th bit = 0) and address frames (9th bit = 1).

The CTS_B pin can be used to control RS-485 output driver outside the chip.

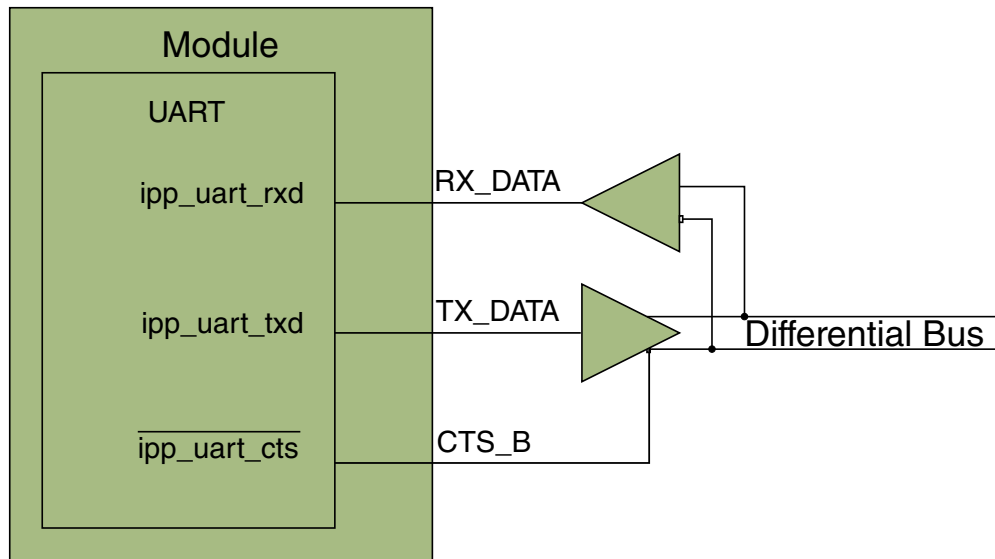

Figure 56-12. RS-485 driver connection (UART in DCE mode)

56.7.2 Transmit 9-bit RS-485 frames

To transmit 9-bit RS-485 frames, user need to enable parity (PREN=1) to enable trasmitting the ninth data bit, set 8-bit data word size (WS=1), and write TXB8 (UMCR[2]) as the 9th bit (bit [8]) to be transmitted (write '0' to TXB8 to transmit a data frame, write '1' to transmit a address frame). The other data bit [7:0] is written to TxFIFO by writing to the UTXD same as normal RS-232 operation.

56.7.3 Receive 9-bit RS-485 frames

To receive 9-bit RS-485 frames, user need to enable parity (PREN=1) to enable receiving the ninth data bit, set 8-bit data word size (WS=1). The receiver will save the 9-bit data to RxFIFO, and user should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

There are two slave address detect modes, normal detect mode and automatic detect mode, and can be selected by SLAM (UMCR[1]).

56.7.3.1 RS-485 Slave Address Normal Detect Mode

To enable Normal Detect mode, clear SLAM (UMCR[1] to 0). The receiver ignores all data frames (9th bit = 0) until an address frame is received (9th bit = 1). At that time, the slave address detected (SAD = USR1[3]) bit is asserted and the *interrupt_uart* interrupt is generated (if SADEN = UMCR[3] = 1). The address byte and subsequent bytes are all put into RxFIFO along with their 9th bit. The UART will also generate DMA request *dma_req_rx* when the RxFIFO reaches the selected threshold (controlled by RXTL) if receive ready DMA (RXDMAEN = UCR1[8]) request is enabled.

User should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

In this mode, once the UART has detected a 9th bit is equal to '1', it will always save the subsequent frames to RxFIFO. So the software must decide whether the address and data in RxFIFO are needed or not.

56.7.3.2 RS-485 Slave Address Automatic Detect Mode

To enable Automatic Detect Mode, set SLAM (UMCR[1]) to 1. The receiver tries to detect an address byte (frame 9th bit = 1) that matches the programmed SLADDR (UMCR[15:8]) character. If the received byte is a data or an address byte that does not match the programmed SLADDR character, the receiver will discard these data.

Once the UART receives a matching address byte, it will assert the slave address detected (SAD = USR1[3]) bit and the *interrupt_uart* interrupt will be generated (if SADEN = UMCR[3] = 1). The address byte and subsequent bytes are all put into RxFIFO along with their 9th bit. If receive ready DMA (RXDMAEN = UCR1[8]) request is enabled, the UART will also generate DMA request *dma_req_rx* when the RxFIFO reaches the selected threshold (controlled by RXTL).

If another address byte is received and this address byte does not match SLADDR character, the receiver will discard the address byte and subsequent data byte. If the address byte again matches SLADDR character, the receiver will put this address byte and subsequent data byte in the RxFIFO along with their 9th bit.

User should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

See [Initialization](#) for 9-bit RS-485 programming guide.

56.8 Low Power Modes

These modes are controlled by the signals *doze_req* and *stop_req*. The control/status/data registers won't change when getting in/out of low power modes.

Table 56-11. UART Low Power State Operation

	Normal State (<i>doze_req</i> = 1'b0 & <i>stop_req</i> = 1'b0)	Doze State (<i>doze_req</i> = 1'b1)		Stop State (<i>stop_req</i> = 1'b1)
		DOZE bit = 0	DOZE bit = 1	
UART-Clock	ON	ON	ON	OFF
UART Serial / IrDA	ON	ON	OFF	OFF

56.8.1 UART Operation in System Doze Mode

While in Doze State (when *doze_req* input pin is set to 1'b1), the UART behavior depends on the DOZE (UCR1[1]) control bit.

While the DOZE bit is negated, the UART serial interface is enabled. While the system is in the Doze State, and the DOZE bit is asserted, the UART is disabled. If the Doze State is entered with the DOZE bit asserted while the UART serial interface was receiving or transmitting data, it will complete the receive/transmit of the current character and signal to the far-end transmitter/receiver to stop sending/receiving.

56.8.2 UART Operation in System Stop Mode

The internal baud rate clocks of the transmitter and receiver are gated off if the *stop_req* signal to UART is asserted. Even though the clocks at the input of the UART continue to run during system Stop mode, the UART will not do any transmission or reception.

The following UART interrupts wake the ARM platform processor from STOP mode:

- RTS (RTSD)
- IrDA Asynchronous WAKE (AIRINT)
- Asynchronous WAKE (AWAKE)
- RI (RIDELT in DTE mode only)
- DCD (DCDDELTA in DTE mode only)
- DTR (DTRD in DCE mode only)
- DSR (DTRD in DTE mode only)

When an asynchronous WAKE (awake) interrupt exits the ARM platform from STOP mode, make sure that a dummy character is sent first because the first character may not be received correctly.

56.8.3 Power Saving Method in UART

The RXEN (UCR2[1]), TXEN (UCR2[2]) and UARTEN (UCR1[0]) bits are set by the user and provide software control of low-power modes.

Setting the UARTEN (UCR1[0]) bit to 0 shuts off the receiver and transmitter logic and the associated clocks.

If the UART is used only in transmit mode, UARTEN and TXEN must be set to 1. If the UART is used only in receive mode, UARTEN and RXEN must be set to 1. Setting TXEN or RXEN to 0 allows to save a lot of power.

56.9 UART Operation in System Debug State

The bit UTS [11] controls whether the UART will respond to the input signal *debug_req*, or whether it will continue to run as normal.

If the UART is programmed to respond to *debug_req*:

1. The UART will halt all operations upon detecting the *debug_req* input.
2. A transfer in progress, either to/from a core (using the IP Bus interface) or to/from an external device, will be completed before halting. This means a single byte/word transfer, not an entire FIFO. Reception of any further data from an external device will be disabled.
3. Internal registers will continue to be writable and readable using the IP Bus interface. A read will leave the contents unaffected.
4. The RX FIFO is affected in debug mode in the following way:
 - All writes into the RX FIFO are prevented.
 - The bit RXDBG (UTS[9]) is used to select the readability of the RX FIFO during debug mode:

RXDBG = 0: hold the read pointer at the location it had upon entering debug mode, and URXD register returns only the data value at that location, no matter how many reads attempted.

RXDBG = 1, selectable at any time: Allow to read the characters received in Rx FIFO. It will not be possible to re-read previously read locations, nor will it be possible to readjust the read pointer to the value it had prior to entering debug mode.

56.10 Reset

This section describes how to reset the block and explains special requirements related to reset.

56.10.1 Hardware reset

All of registers, FIFOs, state machines and sequential elements can be reset to their initial values by hardware reset or power on reset.

56.10.2 Software reset

The status registers USR1 and USR2, BRM registers UBIR and UBMR, TxFIFO and RxFIFO, and transmitter and receiver state machines can be reset by software reset. Internal logic will keep the software reset asserted for about 4 *module_clock* cycles.

Programmer can follow the following software reset sequence:

1. Clear the SRST_B bit (UCR2[0])
2. Wait for software reset complete: poll SOFTRST bit (UTS[0]) until it is 0.
3. Re-program baud rate registers: Re-write UBIR and UBMR.

56.11 Transfer Error

The UART can generate a transfer error on the peripheral bus in the following cases:

- Core is writing into a read-only register.
- Core is accessing (read or write) an unused location within the assigned address space reserved to UART.

- Core is writing into UTXD register with transmit interface disabled (TXEN=0 or UARTEN=0)
- Core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0)

56.12 Functional Timing

This section includes timing diagrams for functional signaling.

56.12.1 IrDA Mode

According to IrDA specification, the low speed (115.2Kbit/s and below) IR frame format is compatible with UART frame.

In this figure, an example data 0x65 is used.

Figure 56-13. Timing diagram of Low Speed IR (<=115.2 Kbit/s) Data Line

56.13 Initialization

56.13.1 Programming the UART in RS-232 mode

As an example, the following sequence can be used to program the UART in order to send and receive characters in RS-232 mode.

Assumptions:

- Input uart clock = 100 MHz
- Baud rate = 921.6 Kbps
- Data bits = 8 bits
- Parity = Even
- Stop bits = 1 bit
- Flow control = Hardware

Main program:

1. UCR1 = 0x0001

Enable the UART.

2. UCR2 = 0x2127

Set hardware flow control, data format and enable transmitter and receiver.

3. UCR3 = 0x0704

Set UCR3[RXDMUXSEL] = 1.

4. UCR4 = 0x7C00

Set CTS trigger level to 31,

5. UFCR = 0x089E

Set internal clock divider = 5 (divide input uart clock by 5). So the reference clock is $100 \text{ MHz}/5 = 20 \text{ MHz}$.

Set TXTL = 2 and RXTL = 30.

6. UBIR = 0x08FF

7. UBMR = 0x0C34

In the above two steps, set baud rate to 921.6Kbps based on the 20MHz reference clock.

8. UCR1 = 0x2201

Enable the TRDY and RRDY interrupts.

9. UMCR = 0x0000

UMCR stay at default value 0x0000

Interrupt service routine for the transmitter:

- Write characters into UTXD

The TRDY interrupt will be automatically de-asserted when the data level of the TxFIFO exceeds the TXTL=2. Note: For the first time the interrupt may be de-asserted after 4 characters are written into the TxFIFO because of the shift register.

Interrupt service routine for the receiver:

- Read characters from URXD

The RRDY interrupt will be automatically de-asserted when the data level of the RxFIFO is below the RXTL=30.

56.13.2 Programming the UART in 9-bit RS-485 mode

As an example, the following sequence can be used to program the UART in order to send and receive frames in RS-485 mode.

Assumptions:

- Input uart clock = 100 MHz
- Baud rate = 5 Mbps

Main program:

1. UCR1 = 0x0001

Enable the UART.

2. UCR2 = 0x4127

Set software flow control ($\overline{\text{CTS}}$ pin is controlled by UCR2[12]), enable parity(enable 9th bit rxd/txd), 8-bit word size , and enable transmitter and receiver.

3. UCR4 = 0x7C00

Set CTS trigger level to 31,

4. UFCR = 0x0A9E

Set RFDIV = 5 (divide input uart clock by 1), so the reference clock is 100 MHz. Set UART in DCE mode (RS-485 driver connection outside the chip is the same as [Figure 56-12](#))

Set TXTL = 2 and RXTL = 30.

5. UBIR = 0x0003
6. UBMR = 0x0004

In the above two steps, set baud rate to 5 Mbps based on the 100 MHz reference clock.

7. UCR1 = 0x2001 when UART as a master ,
or UCR1 = 0x0201 (or 0x0101) when UART as a slave.

Enable TRDY interrupt when UART as a master, enable RRDY interrupt or DMA request when UART as a slave.

8. UMCR = 0xA50B

Enable 9-bit RS-485 mode, enable SAD interrupt, set automatic slave address detect mode, set slave address is 0xA5.

Interrupt service routine for the transmitter:

- Transmit data: write its ninth bit (bit[8]) to UMCR[2], write its bit [7:0] into UTXD[7:0]

The TRDY interrupt will be automatically de-asserted when the data level of the TxFIFO exceeds the TXTL=2.

Note: For the first time the interrupt may be de-asserted after 4 characters are written into the TxFIFO because of the shift register.

Interrupt service routine for the receiver:

- Receive data: read its ninth bit (bit[8]) from URXD[10] , read its bit [7:0] from URXD[7:0].

Note: in RS-485 mode, URXD[10] bit is not the parity error, instead it holds the ninth bit (bit[8]) of the received data.

The SAD interrupt can not de-assert automatically, it needs MCU write 1 to USR1[3] to clear it . The RRDY interrupt or DMA request will be automatically de-asserted when the data level of the RxFIFO is below the RXTL=30.

56.15 UART Memory Map/Register Definition

UART supports 8-bit, 16-bit and 32-bit accesses to 32-bit memory-mapped addresses. Any access to unmapped memory location will yield a transfer error.

All registers except the ONEMS described in this section are 16-bit registers. The ONEMS register is a 24-bit register.

- For 32-bit write accesses, the upper two bytes will not be taken into account.
- For 32-bit read accesses the upper two bytes will return 0.

The ONEMS register is expanded from 16 bits to 24 bits in order to support the high frequency of the BRM internal clock *ref_clk* (*module_clock* after divider). The ONEMS register can be accessed as 8 bits, 16 bits or 32 bits.

- For 32-bit write accesses, the most significant byte of the ONEMS will be discarded.
- For 32-bit read accesses, the most significant byte of the ONEMS will be read as 0.

UART memory map

56.15.1 UART Receiver Register (UARTx_URXD)

NOTE

The UART will yield a transfer error on the peripheral bus when core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0).

Address: Base address + 0h offset

UARTx_URXD field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 CHARRDY	Character Ready. This read-only bit indicates an invalid read when the FIFO becomes empty and software tries to read the same old data. This bit should not be used for polling for data written to the RX FIFO. 0 Character in RX_DATA field and associated flags are invalid. 1 Character in RX_DATA field and associated flags valid and ready for reading.

Table continues on the next page...

UARTx_URXD field descriptions (continued)

Field	Description
14 ERR	<p>Error Detect. Indicates whether the character present in the RX_DATA field has an error (OVRRUN, FRMERR, BRK or PRERR) status. The ERR bit is updated and valid for each received character.</p> <p>0 No error status was detected 1 An error status was detected</p>
13 OVRRUN	<p>Receiver Overrun. This read-only bit, when HIGH, indicates that the corresponding character was stored in the last position (32nd) of the Rx FIFO. Even if a 33rd character has not been detected, this bit will be set to '1' for the 32nd character.</p> <p>0 No RxFIFO overrun was detected 1 A RxFIFO overrun was detected</p>
12 FRMERR	<p>Frame Error. Indicates whether the current character had a framing error (a missing stop bit) and is possibly corrupted. FRMERR is updated for each character read from the RxFIFO.</p> <p>0 The current character has no framing error 1 The current character has a framing error</p>
11 BRK	<p>BREAK Detect. Indicates whether the current character was detected as a BREAK character. The data bits and the stop bit are all 0. The FRMERR bit is set when BRK is set. When odd parity is selected, PRERR is also set when BRK is set. BRK is valid for each character read from the RxFIFO.</p> <p>0 The current character is not a BREAK character 1 The current character is a BREAK character</p>
10 PRERR	<p>In RS-485 mode, it holds the ninth data bit (bit [8]) of received 9-bit RS-485 data</p> <p>In RS232/IrDA mode, it is the Parity Error flag. Indicates whether the current character was detected with a parity error and is possibly corrupted. PRERR is updated for each character read from the RxFIFO. When parity is disabled, PRERR always reads as 0.</p> <p>0 = No parity error was detected for data in the RX_DATA field 1 = A parity error was detected for data in the RX_DATA field</p>
9–8 -	<p>This field is reserved. Reserved</p>
RX_DATA	<p>Received Data. Holds the received character. In 7-bit mode, the most significant bit (MSB) is forced to 0. In 8-bit mode, all bits are active.</p>

56.15.2 UART Transmitter Register (UARTx_UTXD)

NOTE

The UART will yield a transfer error on the peripheral bus when core is writing into UART_URXD register with transmit interface disabled (TXEN=0 or UARTEN=0).

Memory space between UART_URXD and UART_UTXD registers is reserved. Any read or write access to this space will be considered as an invalid access and yield a transfer error.

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

UARTx_UTXD field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–8 Reserved	This read-only field is reserved and always has the value 0.
TX_DATA	Transmit Data. Holds the parallel transmit data inputs. In 7-bit mode, D7 is ignored. In 8-bit mode, all bits are used. Data is transmitted least significant bit (LSB) first. A new character is transmitted when the TX_DATA field is written. The TX_DATA field must be written only when the TRDY bit is high to ensure that corrupted data is not sent.

56.15.3 UART Control Register 1 (UARTx_UCR1)

Address: Base address + 80h offset

UARTx_UCR1 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ADEN	Automatic Baud Rate Detection Interrupt Enable. Enables/Disables the automatic baud rate detect complete (ADET) bit to generate an interrupt (<i>interrupt_uart</i> = 0). 0 Disable the automatic baud rate detection interrupt 1 Enable the automatic baud rate detection interrupt
14 ADBR	Automatic Detection of Baud Rate. Enables/Disables automatic baud rate detection. When the ADBR bit is set and the ADET bit is cleared, the receiver detects the incoming baud rate automatically. The ADET flag is set when the receiver verifies that the incoming baud rate is detected properly by detecting an ASCII character "A" or "a" (0x41 or 0x61). 0 Disable automatic detection of baud rate 1 Enable automatic detection of baud rate
13 TRDYEN	Transmitter Ready Interrupt Enable. Enables/Disables the transmitter Ready Interrupt (TRDY) when the transmitter has one or more slots available in the TxFIFO. The fill level in the TxFIFO at which an interrupt is generated is controlled by TxTL bits. When TRDYEN is negated, the transmitter ready interrupt is disabled. NOTE: An interrupt will be issued as long as TRDYEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TRDY interrupt. 0 Disable the transmitter ready interrupt 1 Enable the transmitter ready interrupt
12 IDEN	Idle Condition Detected Interrupt Enable. Enables/Disables the IDLE bit to generate an interrupt (<i>interrupt_uart</i> = 0). 0 Disable the IDLE interrupt 1 Enable the IDLE interrupt

Table continues on the next page...

UARTx_UCR1 field descriptions (continued)

Field	Description
11–10 ICD	<p>Idle Condition Detect. Controls the number of frames RXD is allowed to be idle before an idle condition is reported.</p> <p>00 Idle for more than 4 frames 01 Idle for more than 8 frames 10 Idle for more than 16 frames 11 Idle for more than 32 frames</p>
9 RRDYEN	<p>Receiver Ready Interrupt Enable. Enables/Disables the RRDY interrupt when the RxFIFO contains data. The fill level in the RxFIFO at which an interrupt is generated is controlled by the RXTL bits. When RRDYEN is negated, the receiver ready interrupt is disabled.</p> <p>0 Disables the RRDY interrupt 1 Enables the RRDY interrupt</p>
8 RXDMAEN	<p>Receive Ready DMA Enable. Enables/Disables the receive DMA request <i>dma_req_rx</i> when the receiver has data in the RxFIFO. The fill level in the RxFIFO at which a DMA request is generated is controlled by the RXTL bits. When negated, the receive DMA request is disabled.</p> <p>0 Disable DMA request 1 Enable DMA request</p>
7 IREN	<p>Infrared Interface Enable. Enables/Disables the IR interface. See the IR interface description in Infrared Interface, for more information.</p> <p>Note: MDEN(UMCR[0]) must be cleared to 0 when using IrDA interface. See Table 56-1</p> <p>0 Disable the IR interface 1 Enable the IR interface</p>
6 TXMPTYEN	<p>Transmitter Empty Interrupt Enable. Enables/Disables the transmitter FIFO empty (TXFE) interrupt. <i>interrupt_uart</i>. When negated, the TXFE interrupt is disabled.</p> <p>NOTE: An interrupt will be issued as long as TXMPTYEN and TXFE are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXFE interrupt.</p> <p>0 Disable the transmitter FIFO empty interrupt 1 Enable the transmitter FIFO empty interrupt</p>
5 RTSDEN	<p>RTS Delta Interrupt Enable. Enables/Disables the RTSD interrupt. The current status of the RTS_B pin is read in the RTSS bit.</p> <p>0 Disable RTSD interrupt 1 Enable RTSD interrupt</p>
4 SNDBRK	<p>Send BREAK. Forces the transmitter to send a BREAK character. The transmitter finishes sending the character in progress (if any) and sends BREAK characters until SNDBRK is reset. Because the transmitter samples SNDBRK after every bit is transmitted, it is important that SNDBRK is asserted high for a sufficient period of time to generate a valid BREAK. After the BREAK transmission completes, the UART transmits 2 mark bits. The user can continue to fill the TxFIFO and any characters remaining are transmitted when the BREAK is terminated.</p> <p>0 Do not send a BREAK character 1 Send a BREAK character (continuous 0s)</p>
3 TXDMAEN	<p>Transmitter Ready DMA Enable. Enables/Disables the transmit DMA request <i>dma_req_tx</i> when the transmitter has one or more slots available in the TxFIFO. The fill level in the TxFIFO that generates the <i>dma_req_tx</i> is controlled by the TXTL bits.</p>

Table continues on the next page...

UARTx_UCR1 field descriptions (continued)

Field	Description
	<p>NOTE: A DMA request will be issued as long as TXDMAEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the transmit DMA request.</p> <p>0 Disable transmit DMA request 1 Enable transmit DMA request</p>
2 ATDMAEN	<p>Aging DMA Timer Enable. Enables/Disables the receive DMA request <i>dma_req_rx</i> for the aging timer interrupt (triggered with AGTIM flag in USR1[8]).</p> <p>0 Disable AGTIM DMA request 1 Enable AGTIM DMA request</p>
1 DOZE	<p>DOZE. Determines the UART enable condition in the DOZE state. When <i>doze_req</i> input pin is at '1', (the ARM Platform executes a doze instruction and the system is placed in the Doze State), the DOZE bit affects operation of the UART. While in the Doze State, if this bit is asserted, the UART is disabled. See the description in Low Power Modes.</p> <p>0 The UART is enabled when in DOZE state 1 The UART is disabled when in DOZE state</p>
0 UARTEN	<p>UART Enable. Enables/Disables the UART. If UARTEN is negated in the middle of a transmission, the transmitter stops and pulls the TXD line to a logic 1. UARTEN must be set to 1 before any access to UTXD and URXD registers, otherwise a transfer error is returned.</p> <p>This bit can be set to 1 along with other bits in this register. There is no restriction to the sequence of programing this bit and other control registers.</p> <p>0 Disable the UART 1 Enable the UART</p>

56.15.4 UART Control Register 2 (UARTx_UCR2)

Address: Base address + 84h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

UARTx_UCR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ESCI	Escape Sequence Interrupt Enable. Enables/Disables the ESCF bit to generate an interrupt. 0 Disable the escape sequence interrupt 1 Enable the escape sequence interrupt
14 IRTS	Ignore RTS Pin. Forces the RTS input signal presented to the transmitter to always be asserted (set to low), effectively ignoring the external pin. When in this mode, the RTS pin serves as a general purpose input. 0 Transmit only when the RTS pin is asserted 1 Ignore the RTS pin
13 CTSC	CTS Pin Control. Controls the operation of the CTS_B module output. When CTSC is asserted, the CTS_B module output is controlled by the receiver. When the RxFIFO is filled to the level of the programmed trigger level and the start bit of the overflowing character (TRIGGER LEVEL + 1) is validated, the CTS_B module output is negated to indicate to the far-end transmitter to stop transmitting. When the trigger level is programmed for less than 32, the receiver continues to receive data until the RxFIFO is full. When the CTSC bit is negated, the CTS_B module output is controlled by the CTS bit. On reset, because CTSC is cleared to 0, the CTS_B pin is controlled by the CTS bit, which again is cleared to 0 on reset. This means that on reset the CTS_B signal is negated. 0 The CTS_B pin is controlled by the CTS bit 1 The CTS_B pin is controlled by the receiver
12 CTS	Clear to Send. Controls the CTS_B pin when the CTSC bit is negated. CTS has no function when CTSC is asserted. 0 The CTS_B pin is high (inactive) 1 The CTS_B pin is low (active)
11 ESSEN	Escape Enable. Enables/Disables the escape sequence detection logic. 0 Disable escape sequence detection 1 Enable escape sequence detection
10–9 RTEC	Request to Send Edge Control. Selects the edge that triggers the RTS interrupt. This has no effect on the RTS delta interrupt. RTEC has an effect only when RTSEN = 1 (see Table 56-5). 00 Trigger interrupt on a rising edge 01 Trigger interrupt on a falling edge 1X Trigger interrupt on any edge
8 PREN	Parity Enable. Enables/Disables the parity generator in the transmitter and parity checker in the receiver. When PREN is asserted, the parity generator and checker are enabled, and disabled when PREN is negated. 0 Disable parity generator and checker 1 Enable parity generator and checker
7 PROE	Parity Odd/Even. Controls the sense of the parity generator and checker. When PROE is high, odd parity is generated and expected. When PROE is low, even parity is generated and expected. PROE has no function if PREN is low. 0 Even parity 1 Odd parity

Table continues on the next page...

UARTx_UCR2 field descriptions (continued)

Field	Description
6 STPB	<p>Stop. Controls the number of stop bits after a character. When STPB is low, 1 stop bit is sent. When STPB is high, 2 stop bits are sent. STPB also affects the receiver.</p> <p>0 The transmitter sends 1 stop bit. The receiver expects 1 or more stop bits. 1 The transmitter sends 2 stop bits. The receiver expects 2 or more stop bits.</p>
5 WS	<p>Word Size. Controls the character length. When WS is high, the transmitter and receiver are in 8-bit mode. When WS is low, they are in 7-bit mode. The transmitter ignores bit 7 and the receiver sets bit 7 to 0. WS can be changed in-between transmission (reception) of characters, however not when a transmission (reception) is in progress, in which case the length of the current character being transmitted (received) is unpredictable.</p> <p>0 7-bit transmit and receive character length (not including START, STOP or PARITY bits) 1 8-bit transmit and receive character length (not including START, STOP or PARITY bits)</p>
4 RTSEN	<p>Request to Send Interrupt Enable. Controls the RTS edge sensitive interrupt. When RTSEN is asserted and the programmed edge is detected on the RTS_B pin (the RTSF bit is asserted), an interrupt will be generated on the <i>interrupt_uart</i> pin. (See Table 56-5.)</p> <p>0 Disable request to send interrupt 1 Enable request to send interrupt</p>
3 ATEN	<p>Aging Timer Enable. This bit is used to enable the aging timer interrupt (triggered with AGTIM)</p> <p>0 AGTIM interrupt disabled 1 AGTIM interrupt enabled</p>
2 TXEN	<p>Transmitter Enable. Enables/Disables the transmitter. When TXEN is negated the transmitter is disabled and idle. When the UARTEN and TXEN bits are set the transmitter is enabled. If TXEN is negated in the middle of a transmission, the UART disables the transmitter immediately, and starts marking 1s. The transmitter FIFO cannot be written when this bit is cleared.</p> <p>0 Disable the transmitter 1 Enable the transmitter</p>
1 RXEN	<p>Receiver Enable. Enables/Disables the receiver. When the receiver is enabled, if the RXD input is already low, the receiver does not recognize BREAK characters, because it requires a valid 1-to-0 transition before it can accept any character.</p> <p>0 Disable the receiver 1 Enable the receiver</p>
0 SRST	<p>Software Reset. Once the software writes 0 to SRST_B, the software reset remains active for 4 <i>module_clock</i> cycles before the hardware deasserts SRST_B. The software can only write 0 to SRST_B. Writing 1 to SRST_B is ignored.</p> <p>0 Reset the transmit and receive state machines, all FIFOs and register USR1, USR2, UBIR, UBMR, UBRC, URXD, UTXD and UTS[6-3]. 1 No reset</p>

56.15.5 UART Control Register 3 (UARTx_UCR3)

Address: Base address + 88h offset

UARTx_UCR3 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–14 DPEC	DTR/DSR Interrupt Edge Control. These bits control the edge of DTR_B (DCE) or DSR_B (DTE) on which an interrupt will be generated. An interrupt will only be generated if the DTREN bit is set. 00 interrupt generated on rising edge 01 interrupt generated on falling edge 1X interrupt generated on either edge
13 DTREN	Data Terminal Ready Interrupt Enable. When this bit is set, it will enable the status bit DTRF (USR2 [13]) (DTR/DSR edge sensitive interrupt) to cause an interrupt. 0 Data Terminal Ready Interrupt Disabled 1 Data Terminal Ready Interrupt Enabled
12 PARERREN	Parity Error Interrupt Enable. Enables/Disables the interrupt. When asserted, PARERREN causes the PARITYERR bit to generate an interrupt. 0 Disable the parity error interrupt 1 Enable the parity error interrupt
11 FRAERREN	Frame Error Interrupt Enable. Enables/Disables the interrupt. When asserted, FRAERREN causes the FRAMERR bit to generate an interrupt. 0 Disable the frame error interrupt 1 Enable the frame error interrupt
10 DSR	Data Set Ready. This bit is used by software to control the DSR/DTR module output for the modem interface. In DCE mode it applies to DSR_B and in DTE mode it applies to DTR_B. 0 DSR/ DTR pin is logic zero 1 DSR/ DTR pin is logic one

Table continues on the next page...

UARTx_UCR3 field descriptions (continued)

Field	Description
9 DCD	<p>Data Carrier Detect. In DCE mode this bit is used by software to control the DCD_B module output for the modem interface. In DTE mode, when this bit is set, it will enable the status bit DCDELT (USR2 (6)) to cause an interrupt.</p> <p>0 DCD_B pin is logic zero (DCE mode) 1 DCD_B pin is logic one (DCE mode) 0 DCDELT interrupt disabled (DTE mode) 1 DCDELT interrupt enabled (DTE mode)</p>
8 RI	<p>Ring Indicator. In DCE mode this bit is used by software to control the RI_B module output for the modem interface. In DTE mode, when this bit is set, it will enable the status bit RIDELT (USR2 (10)) to cause an interrupt.</p> <p>0 RI_B pin is logic zero (DCE mode) 1 RI_B pin is logic one (DCE mode) 0 RIDELT interrupt disabled (DTE mode) 1 RIDELT interrupt enabled (DTE mode)</p>
7 ADNIMP	<p>Autobaud Detection Not Improved- Disables new features of autobaud detection (See Baud Rate Automatic Detection Protocol, for more details).</p> <p>0 Autobaud detection new features selected 1 Keep old autobaud detection mechanism</p>
6 RXDSEN	<p>Receive Status Interrupt Enable. Controls the receive status interrupt (<i>interrupt_uart</i>). When this bit is enabled and RXDS status bit is set, the interrupt <i>interrupt_uart</i> will be generated.</p> <p>0 Disable the RXDS interrupt 1 Enable the RXDS interrupt</p>
5 AIRINTEN	<p>Asynchronous IR WAKE Interrupt Enable. Controls the asynchronous IR WAKE interrupt. An interrupt is generated when AIRINTEN is asserted and a pulse is detected on the RXD pin.</p> <p>0 Disable the AIRINT interrupt 1 Enable the AIRINT interrupt</p>
4 AWAKEN	<p>Asynchronous WAKE Interrupt Enable. Controls the asynchronous WAKE interrupt. An interrupt is generated when AWAKEN is asserted and a falling edge is detected on the RXD pin.</p> <p>0 Disable the AWAKE interrupt 1 Enable the AWAKE interrupt</p>
3 DTRDEN	<p>Data Terminal Ready Delta Enable. Enables / Disables the asynchronous DTRD interrupt. When DTRDEN is asserted and an edge (rising or falling) is detected on DTR_B (in DCE mode) or on DSR_B (in DTE mode), then an interrupt is generated.</p> <p>0 Disable DTRD interrupt 1 Enable DTRD interrupt</p>
2 RXDMUXSEL	<p>RXD Muxed Input Selected. Selects proper input pins for serial and Infrared input signal.</p> <p>NOTE: In this chip, UARTs are used in MUXED mode, so that this bit should always be set.</p>
1 INVT	<p>Invert TXD output in RS-232/RS-485 mode, set TXD active level in IrDA mode.</p> <p>In RS232/RS-485 mode(UMCR[0] = 1), if this bit is set to 1, the TXD output is inverted before transmitted.</p> <p>In IrDA mode, when INVT is cleared, the infrared logic block transmits a positive IR 3/16 pulse for all 0s and 0s are transmitted for 1s. When INVT is set (INVT = 1), the infrared logic block transmits an active low or negative infrared 3/16 pulse for all 0s and 1s are transmitted for 1s.</p>

Table continues on the next page...

UARTx_UCR3 field descriptions (continued)

Field	Description
	0 TXD is not inverted 1 TXD is inverted 0 TXD Active low transmission 1 TXD Active high transmission
0 ACIEN	Autobaud Counter Interrupt Enable. This bit is used to enable the autobaud counter stopped interrupt (triggered with ACST (USR2[11]). 0 ACST interrupt disabled 1 ACST interrupt enabled

UARTx_UCR4 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–10 CTSTL	CTS Trigger Level. Controls the threshold at which the CTS_B pin is deasserted by the RxFIFO. After the trigger level is reached and the CTS_B pin is deasserted, the RxFIFO continues to receive data until it is full. The CTSTL bits are encoded as shown in the Settings column. Settings 0 to 32 are in use. All other settings are Reserved. 000000 0 characters received 000001 1 characters in the RxFIFO ... — ... — 100000 32 characters in the RxFIFO (maximum)
9 INVR	Invert RXD input in RS-232/RS-485 Mode, determine RXD input logic level being sampled in In IrDA mode.

Table continues on the next page...

UARTx_UCR4 field descriptions (continued)

Field	Description
	<p>In RS232/RS-485 Mode(UMCR[0] = 1), if this bit is set to 1, the RXD input is inverted before sampled.</p> <p>In IrDA mode,when cleared, the infrared logic block expects an active low or negative IR 3/16 pulse for 0s and 1s are expected for 1s. When INVR is set (INVR 1), the infrared logic block expects an active high or positive IR 3/16 pulse for 0s and 0s are expected for 1s.</p> <p>0 RXD input is not inverted 1 RXD input is inverted 0 RXD active low detection 1 RXD active high detection</p>
8 ENIRI	<p>Serial Infrared Interrupt Enable. Enables/Disables the serial infrared interrupt.</p> <p>0 Serial infrared Interrupt disabled 1 Serial infrared Interrupt enabled</p>
7 WKEN	<p>WAKE Interrupt Enable. Enables/Disables the WAKE bit to generate an interrupt. The WAKE bit is set at the detection of a start bit by the receiver.</p> <p>0 Disable the WAKE interrupt 1 Enable the WAKE interrupt</p>
6 IDDMAEN	<p>DMA IDLE Condition Detected Interrupt Enable Enables/Disables the receive DMA request <i>dma_req_rx</i> for the IDLE interrupt (triggered with IDLE flag in USR2[12]).</p> <p>0 DMA IDLE interrupt disabled 1 DMA IDLE interrupt enabled</p>
5 IRSC	<p>IR Special Case. Selects the clock for the vote logic. When set, IRSC switches the vote logic clock from the sampling clock to the UART reference clock. The IR pulses are counted a predetermined amount of time depending on the reference frequency. See InfraRed Special Case (IRSC) Bit.</p> <p>0 The vote logic uses the sampling clock (16x baud rate) for normal operation 1 The vote logic uses the UART reference clock</p>
4 LPBYP	<p>Low Power Bypass. Allows to bypass the low power new features in UART. To use during debug phase.</p> <p>0 Low power features enabled 1 Low power features disabled</p>
3 TCEN	<p>TransmitComplete Interrupt Enable. Enables/Disables the TXDC bit to generate an interrupt (<i>interrupt_uart = 0</i>)</p> <p>NOTE: An interrupt will be issued as long as TCEN and TXDC are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXDC interrupt.</p> <p>0 Disable TXDC interrupt 1 Enable TXDC interrupt</p>
2 BKEN	<p>BREAK Condition Detected Interrupt Enable. Enables/Disables the BRCD bit to generate an interrupt.</p> <p>0 Disable the BRCD interrupt 1 Enable the BRCD interrupt</p>
1 OREN	<p>Receiver Overrun Interrupt Enable. Enables/Disables the ORE bit to generate an interrupt.</p> <p>0 Disable ORE interrupt 1 Enable ORE interrupt</p>

Table continues on the next page...

UARTx_UFCR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–10 TXTL	Transmitter Trigger Level. Controls the threshold at which a maskable interrupt is generated by the TxFIFO. A maskable interrupt is generated whenever the data level in the TxFIFO falls below the selected threshold. The bits are encoded as shown in the Settings column. Settings 0 to 32 are in use. All other settings are Reserved. 000000 Reserved 000001 Reserved 000010 TxFIFO has 2 or fewer characters ... — ... — 011111 TxFIFO has 31 or fewer characters 100000 TxFIFO has 32 characters (maximum)
9–7 RFDIV	Reference Frequency Divider. Controls the divide ratio for the reference clock. The input clock is <i>module_clock</i> . The output from the divider is <i>ref_clk</i> which is used by BRM to create the 16x baud rate oversampling clock (<i>brm_clk</i>). 000 Divide input clock by 6 001 Divide input clock by 5

Table continues on the next page...

UARTx_UFCR field descriptions (continued)

Field	Description
	010 Divide input clock by 4 011 Divide input clock by 3 100 Divide input clock by 2 101 Divide input clock by 1 110 Divide input clock by 7 111 Reserved
6 DCEDTE	<p>DCE/DTE mode select. Select UART as data communication equipment (DCE mode) or as data terminal equipment (DTE mode).</p> 0 DCE mode selected 1 DTE mode selected
RXTL	<p>Receiver Trigger Level. Controls the threshold at which a maskable interrupt is generated by the RxFIFO. A maskable interrupt is generated whenever the data level in the RxFIFO reaches the selected threshold. The RXTL bits are encoded as shown in the Settings column.</p> <p>Setting 0 to 32 are in use. All other settings are Reserved.</p> 000000 0 characters received 000001 RxFIFO has 1 character ... — ... — 011111 RxFIFO has 31 characters 100000 RxFIFO has 32 characters (maximum)

56.15.8 UART Status Register 1 (UARTx_USR1)

Address: Base address + 94h offset

UARTx_USR1 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 PARITYERR	Parity Error Interrupt Flag. Indicates a parity error is detected. PARITYERR is cleared by writing 1 to it. Writing 0 to PARITYERR has no effect. When parity is disabled, PARITYERR always reads 0. At reset, PARITYERR is set to 0. 0 No parity error detected 1 Parity error detected (write 1 to clear)
14 RTSS	RTS_B Pin Status. Indicates the current status of the RTS_B pin. A "snapshot" of RTS_B is taken immediately before RTSS is presented to the data bus. RTSS cannot be cleared because all writes to RTSS are ignored. At reset, RTSS is set to 0.

Table continues on the next page...

UARTx_USR1 field descriptions (continued)

Field	Description
	0 The RTS_B module input is high (inactive) 1 The RTS_B module input is low (active)
13 TRDY	Transmitter Ready Interrupt / DMA Flag. Indicates that the TxFIFO emptied below its target threshold and requires data. TRDY is automatically cleared when the data level in the TxFIFO exceeds the threshold set by TXTL bits. At reset, TRDY is set to 1. 0 The transmitter does not require data 1 The transmitter requires data (interrupt posted)
12 RTSD	RTS Delta. Indicates whether the RTS_B pin changed state. It (RTSD) generates a maskable interrupt. When in STOP mode, RTS assertion sets RTSD and can be used to wake the processor. The current state of the RTS_B pin is available on the RTSS bit. Clear RTSD by writing 1 to it. Writing 0 to RTSD has no effect. At reset, RTSD is set to 0. 0 RTS_B pin did not change state since last cleared 1 RTS_B pin changed state (write 1 to clear)
11 ESCF	Escape Sequence Interrupt Flag. Indicates if an escape sequence was detected. ESCF is asserted when the ESCEN bit is set and an escape sequence is detected in the RxFIFO. Clear ESCF by writing 1 to it. Writing 0 to ESCF has no effect. 0 No escape sequence detected 1 Escape sequence detected (write 1 to clear).
10 FRAMERR	Frame Error Interrupt Flag. Indicates that a frame error is detected. The <i>interrupt_uart</i> interrupt will be generated if a frame error is detected and the interrupt is enabled. Clear FRAMERR by writing 1 to it. Writing 0 to FRAMERR has no effect. 0 No frame error detected 1 Frame error detected (write 1 to clear)
9 RRDY	Receiver Ready Interrupt / DMA Flag. Indicates that the RxFIFO data level is above the threshold set by the RXTL bits. (See the RXTL bits description in UART FIFO Control Register (UART_UFCR) for setting the interrupt threshold.) When asserted, RRDY generates a maskable interrupt or DMA request. RRDY is automatically cleared when data level in the RxFIFO goes below the set threshold level. At reset, RRDY is set to 0. 0 No character ready 1 Character(s) ready (interrupt posted)
8 AGTIM	Ageing Timer Interrupt Flag. Indicates that data in the RxFIFO has been idle for a time of 8 character lengths (where a character length consists of 7 or 8 bits, depending on the setting of the WS bit in UCR2, with the bit time corresponding to the baud rate setting) and FIFO data level is less than RxFIFO threshold level (RXTL in the UFCR). Clear by writing a 1 to it. 0 AGTIM is not active 1 AGTIM is active (write 1 to clear)
7 DTRD	DTR Delta. Indicates whether DTR_B (in DCE mode) or DSR_B (in DTE mode) pins changed state. DTRD generates a maskable interrupt if DTRDEN (UCR3[3]) is set. Clear DTRD by writing 1 to it. Writing 0 to DTRD has no effect. 0 DTR_B (DCE) or DSR_B (DTE) pin did not change state since last cleared 1 DTR_B (DCE) or DSR_B (DTE) pin changed state (write 1 to clear)
6 RXDS	Receiver IDLE Interrupt Flag. Indicates that the receiver state machine is in an IDLE state, the next state is IDLE, and the receive pin is high. RXDS is automatically cleared when a character is received. RXDS is active only when the receiver is enabled.

Table continues on the next page...

UARTx_USR1 field descriptions (continued)

Field	Description
	0 Receive in progress 1 Receiver is IDLE
5 AIRINT	Asynchronous IR WAKE Interrupt Flag. Indicates that the IR WAKE pulse was detected on the RXD pin. Clear AIRINT by writing 1 to it. Writing 0 to AIRINT has no effect. 0 No pulse was detected on the RXD IrDA pin 1 A pulse was detected on the RXD IrDA pin
4 AWAKE	Asynchronous WAKE Interrupt Flag. Indicates that a falling edge was detected on the RXD pin. Clear AWAKE by writing 1 to it. Writing 0 to AWAKE has no effect. 0 No falling edge was detected on the RXD Serial pin 1 A falling edge was detected on the RXD Serial pin
3 SAD	RS-485 Slave Address Detected Interrupt Flag. Indicates if RS-485 Slave Address was detected . SAD was asserted in RS-485 mode when the SADEN bit is set and Slave Address is detected in RxFIFO (in Nomal Address Detect Mode, the 9 th data bit = 1; in Automatic Address Detect Mode, the received charater matches the programmed SLADDR). 0 No slave address detected 1 Slave address detected
-	This field is reserved. Reserved

56.15.9 UART Status Register 2 (UARTx_USR2)

Address: Base address + 98h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

UARTx_USR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ADET	Automatic Baud Rate Detect Complete. Indicates that an "A" or "a" was received and that the receiver detected and verified the incoming baud rate. Clear ADET by writing 1 to it. Writing 0 to ADET has no effect. 0 ASCII "A" or "a" was not received 1 ASCII "A" or "a" was received (write 1 to clear)
14 TXFE	Transmit Buffer FIFO Empty. Indicates that the transmit buffer (TxFIFO) is empty. TXFE is cleared automatically when data is written to the TxFIFO. Even though TXFE is high, the transmission might still be in progress. 0 The transmit buffer (TxFIFO) is not empty 1 The transmit buffer (TxFIFO) is empty

Table continues on the next page...

UARTx_USR2 field descriptions (continued)

Field	Description
13 DTRF	DTR edge triggered interrupt flag. This bit is asserted, when the programmed edge is detected on the DTR_B pin (DCE mode) or on DSR_B (DTE mode). This flag can cause an interrupt if DTREN (UCR3[13]) is enabled. 0 Programmed edge not detected on DTR/DSR 1 Programmed edge detected on DTR/DSR (write 1 to clear)
12 IDLE	Idle Condition. Indicates that an idle condition has existed for more than a programmed amount frame (see Idle Line Detect). An interrupt can be generated by this IDLE bit if IDEN (UCR1[12]) is enabled. IDLE is cleared by writing 1 to it. Writing 0 to IDLE has no effect. 0 No idle condition detected 1 Idle condition detected (write 1 to clear)
11 ACST	Autobaud Counter Stopped. In autobaud detection (ADBR=1), indicates the counter which determines the baud rate was running and is now stopped. This means either START bit is finished (if ADNIMP=1), or Bit 0 is finished (if ADNIMP=0). See New Autobaud Counter Stopped bit and Interrupt , for more details. An interrupt can be flagged on <i>interrupt_uart</i> if ACIEN=1. 0 Measurement of bit length not finished (in autobaud) 1 Measurement of bit length finished (in autobaud). (write 1 to clear)
10 RIDELT	Ring Indicator Delta. This bit is used in DTE mode to indicate that the Ring Indicator input (RI_B) has changed state. This flag can generate an interrupt if RI (UCR3[8]) is enabled. RIDELT is cleared by writing 1 to it. Writing 0 to RIDELT has no effect. 0 Ring Indicator input has not changed state 1 Ring Indicator input has changed state (write 1 to clear)
9 RIIN	Ring Indicator Input. This bit is used in DTE mode to reflect the status if the Ring Indicator input (RI_B). The Ring Indicator input is used to indicate that a ring has occurred. In DCE mode this bit is always zero. 0 Ring Detected 1 No Ring Detected
8 IRINT	Serial Infrared Interrupt Flag. When an edge is detected on the RXD pin during SIR Mode, this flag will be asserted. This flag can cause an interrupt which can be masked using the control bit ENIRI: UCR4 [8]. 0 no edge detected 1 valid edge detected (write 1 to clear)
7 WAKE	Wake. Indicates the start bit is detected. WAKE can generate an interrupt that can be masked using the WKEN bit. Clear WAKE by writing 1 to it. Writing 0 to WAKE has no effect. 0 start bit not detected 1 start bit detected (write 1 to clear)
6 DCDDELTA	Data Carrier Detect Delta. This bit is used in DTE mode to indicate that the Data Carrier Detect input (DCD_B) has changed state. This flag can cause an interrupt if DCD (UCR3[9]) is enabled. When in STOP mode, this bit can be used to wake the processor. In DCE mode this bit is always zero. 0 Data Carrier Detect input has not changed state 1 Data Carrier Detect input has changed state (write 1 to clear)
5 DCDIN	Data Carrier Detect Input. This bit is used in DTE mode reflect the status of the Data Carrier Detect input (DCD_B). The Data Carrier Detect input is used to indicate that a carrier signal has been detected. In DCE mode this bit is always zero.

Table continues on the next page...

UARTx_USR2 field descriptions (continued)

Field	Description
	0 Carrier signal Detected 1 No Carrier signal Detected
4 RTSF	RTS Edge Triggered Interrupt Flag. Indicates if a programmed edge is detected on the RTS_B pin. The RTEC bits select the edge that generates an interrupt (see Table 56-5). RTSF can generate an interrupt that can be masked using the RTSEN bit. Clear RTSF by writing 1 to it. Writing 0 to RTSF has no effect. 0 Programmed edge not detected on RTS_B 1 Programmed edge detected on RTS_B (write 1 to clear)
3 TXDC	Transmitter Complete. Indicates that the transmit buffer (TxFIFO) and Shift Register is empty; therefore the transmission is complete. TXDC is cleared automatically when data is written to the TxFIFO. 0 Transmit is incomplete 1 Transmit is complete
2 BRCD	BREAK Condition Detected. Indicates that a BREAK condition was detected by the receiver. Clear BRCD by writing 1 to it. Writing 0 to BRCD has no effect. 0 No BREAK condition was detected 1 A BREAK condition was detected (write 1 to clear)
1 ORE	Overflow Error. When set to 1, ORE indicates that the receive buffer (RxFIFO) was full (32 chars inside), and a 33rd character has been fully received. This 33rd character has been discarded. Clear ORE by writing 1 to it. Writing 0 to ORE has no effect. 0 No overrun error 1 Overrun error (write 1 to clear)
0 RDR	Receive Data Ready- Indicates that at least 1 character is received and written to the RxFIFO. If the URXD register is read and there is only 1 character in the RxFIFO, RDR is automatically cleared. 0 No receive data ready 1 Receive data ready

56.15.10 UART Escape Character Register (UARTx_UESC)

Address: Base address + 9Ch offset

UARTx_UESC field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
ESC_CHAR	UART Escape Character. Holds the selected escape character that all received characters are compared against to detect an escape sequence.

56.15.11 UART Escape Timer Register (UARTx_UTIM)

Address: Base address + A0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																TIM															
W	0																0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UARTx_UTIM field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value 0.
TIM	UART Escape Timer. Holds the maximum time interval (in ms) allowed between escape characters. The escape timer register is programmable in intervals of 2 ms. See Escape Sequence Detection and Table 56-10 for more information on the UART escape sequence detection. Reset value 0x000 = 2 ms up to 0xFFFF = 8.192 s.

56.15.12 UART BRM Incremental Register (UARTx_UBIR)

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write 0x000F value into the UBIR after finishing detecting baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle³.

Please note software reset will reset the register to its reset value.

Address: Base address + A4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																INC															
W	0																0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UARTx_UBIR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
INC	Incremental Numerator. Holds the numerator value minus one of the BRM ratio (see Binary Rate Multiplier (BRM)). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM will ignore this data until the other register is written to by software. Updating this field using byte accesses is not recommended and is undefined.

3. Note: The write priority in the new design is not same as the original UART. In the original design, software has higher priority than hardware when writing this register at the same time.

56.15.13 UART BRM Modulator Register (UARTx_UBMR)

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write a proper value into the UBMR based on detected baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle⁴.

Please note software reset will reset the register to its reset value.

Address: Base address + A8h offset

UARTx_UBMR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
MOD	Modulator Denominator. Holds the value of the denominator minus one of the BRM ratio (see Binary Rate Multiplier (BRM)). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM will ignore this data until the other register is written to by software. Updating this register using byte accesses is not recommended and undefined.

56.15.14 UART Baud Rate Count Register (UARTx_UBRC)

Address: Base address + ACh offset

UARTx_UBRC field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
BCNT	Baud Rate Count Register. This read only register is used to count the start bit of the incoming baud rate (if ADNIMP=1), or start bit + bit0 (if ADNIMP=0). When the measurement is done, the Baud Rate Count Register contains the number of UART internal clock cycles (clock after divider) present in an incoming bit. BCNT retains its value until the next Automatic Baud Rate Detection sequence has been initiated. The 16 bit Baud Rate Count register is reset to 4 and stays at hex FFFF in the case of an overflow.

4. Note: The write priority in the new design is not same as the original UART. In the original design, software has higher priority than hardware when writing this register at the same time.

56.15.15 UART One Millisecond Register (UARTx_ONEMS)

NOTE

This register has been expanded from 16 bits to 24 bits. In previous versions, the 16-bit ONEMS can only support the maximum 65.535MHz (0xFFFFx1000) *ref_clk*. To support 4Mbps Bluetooth application with 66.5MHz *module_clock*, the value 0x103C4 (66.5M/1000) should be written into this register. In this case, the 16 bits are not enough to contain the 0x103C4. So this register was expanded to 24 bits to support high frequency of the *ref_clk*.

Address: Base address + B0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								ONEMS																							
W	0								0																							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

UARTx_ONEMS field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
ONEMS	<p>One Millisecond Register. This 24-bit register must contain the value of the UART internal frequency (<i>ref_clk</i> in Figure 56-1) divided by 1000. The internal frequency is obtained after the UART BRM internal divider ($F(\text{ref_clk}) = F(\text{module_clock}) / \text{RFDIV}$).</p> <p>In fact this register contains the value corresponding to the number of UART BRM internal clock cycles present in one millisecond.</p> <p>The ONEMS (and UTIM) registers value are used in the escape character detection feature (Escape Sequence Detection) to count the number of clock cycles left between two escape characters. The ONEMS register is also used in infrared special case mode (IRSC = UCR4[5] = 1'b1), see InfraRed Special Case (IRSC) Bit.</p>

56.15.16 UART Test Register (UARTx_UTS)

Address: Base address + B4h offset

UARTx_UTS field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
13 FRCPERR	Force Parity Error. Forces the transmitter to generate a parity error if parity is enabled. FRCPERR is provided for system debugging. 0 Generate normal parity 1 Generate inverted parity (error)
12 LOOP	Loop TX and RX for Test. Controls loopback for test purposes. When LOOP is high, the receiver input is internally connected to the transmitter and ignores the RXD pin. The transmitter is unaffected by LOOP. If RXDMUXSEL (UCR3[2]) is set to 1, the loopback is applied on serial and IrDA signals. If RXDMUXSEL is set to 0, the loopback is only applied on serial signals. 0 Normal receiver operation 1 Internally connect the transmitter output to the receiver input
11 DBGEN	debug_enable_B. This bit controls whether to respond to the <i>debug_req</i> input signal. 0 UART will go into debug mode when <i>debug_req</i> is HIGH 1 UART will not go into debug mode even if <i>debug_req</i> is HIGH
10 LOOPIR	Loop TX and RX for IR Test (LOOPIR) . This bit controls loopback from transmitter to receiver in the InfraRed interface. 0 No IR loop 1 Connect IR transmitter to IR receiver
9 RXDBG	RX_fifo_debug_mode . This bit controls the operation of the RX fifo read counter when in debug mode. 0 rx fifo read pointer does not increment 1 rx_fifo read pointer increments as normal

Table continues on the next page...

UARTx_UTS field descriptions (continued)

Field	Description
8–7 Reserved	This read-only field is reserved and always has the value 0.
6 TXEMPTY	TxFIFO Empty. Indicates that the TxFIFO is empty. 0 The TxFIFO is not empty 1 The TxFIFO is empty
5 RXEMPTY	RxFIFO Empty. Indicates the RxFIFO is empty. 0 The RxFIFO is not empty 1 The RxFIFO is empty
4 TXFULL	TxFIFO FULL. Indicates the TxFIFO is full. 0 The TxFIFO is not full 1 The TxFIFO is full
3 RXFULL	RxFIFO FULL. Indicates the RxFIFO is full. 0 The RxFIFO is not full 1 The RxFIFO is full
2–1 Reserved	This read-only field is reserved and always has the value 0.
0 SOFTTRST	Software Reset. Indicates the status of the software reset (SRST_B bit of UCR2). 0 Software reset inactive 1 Software reset active

56.15.17 UART RS-485 Mode Control Register (UARTx_UMCR)

Address: Base address + B8h offset

UARTx_UMCR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–8 SLADDR	RS-485 Slave Address Character. Holds the selected slave address character that the receiver will try to detect.
7–4 Reserved	This read-only field is reserved and always has the value 0.
3 SADEN	RS-485 Slave Address Detected Interrupt Enable. 0 Disable RS-485 Slave Address Detected Interrupt 1 Enable RS-485 Slave Address Detected Interrupt
2 TXB8	Transmit RS-485 bit 8 (the ninth bit or 9 th bit). In RS-485 mode, software writes TXB8 bit as the 9 th data bit to be transmitted. 0 0 will be transmitted as the RS485 9 th data bit 1 1 will be transmitted as the RS485 9 th data bit
1 SLAM	RS-485 Slave Address Detect Mode Selection. 0 Select Normal Address Detect mode 1 Select Automatic Address Detect mode
0 MDEN	9-bit data or Multidrop Mode (RS-485) Enable. 0 Normal RS-232 or IrDA mode, see Table 56-1 for detail. 1 Enable RS-485 mode, see Table 56-1 for detail

Chapter 57

Universal Serial Bus Controller (USB)

57.1 Overview

The USB controller block provides high performance USB functionality that conforms to the *Universal Serial Bus Specification, Rev. 2.0* (Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips; 2000), and the *On-The-Go and Embedded Host Supplement to the USB Revision 2.0 Specification* (Hewlett-Packard Company, Intel Corporation, LSI Corporation, Microsoft Corporation, Renesas Electronics Corporation, ST-Ericsson; 2012).

The USB controller consists of independent USB controller cores: two On-The-Go (OTG) controller cores. Each controller core supports UTMI interface. See [Features](#) for more details. controller cores are single-port cores. For the OTG cores, there is only one port. The port can be used as either a downstream or an upstream port.

The following figure is a block diagram of USB.

57.1.1 Features

There are USB 2.0 controller cores in this chip:

- Controller Core 0 is also named 'OTG1 Core'; its connected port is named 'OTG1 port'.
- Controller Core 1 is also named 'OTG2 Core'; its connected port is named 'OTG2 port'.

The following list provides features of each of the controller cores.

- USB 2.0 Controller Core 0
 - High-Speed/Full-Speed/Low-Speed OTG core
 - HS/FS/LS UTMI compliant interface

- High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
- High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
- Hardware support for OTG signaling, session request protocol, and host negotiation protocol
- Up to 8 bidirectional endpoints
- Support charger detection
- USB 2.0 Controller Core 1
 - High-Speed/Full-Speed/Low-Speed OTG core
 - HS/FS/LS UTMI compliant interface
 - High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
 - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
 - Hardware support for OTG signaling, session request protocol, and host negotiation protocol
 - Up to 8 bidirectional endpoints
- Low-power mode with local and remote wake-up capability
- Serial PHY interfaces configurable for bidirectional/unidirectional and differential/single ended
- Embedded DMA controller in each core

57.1.2 Modes of Operation

The USB has two main modes of operation: normal mode and low power mode.

Each USB OTG controller core can operate in High Speed operation (480 Mbps), Full Speed operation (12 Mbps) and Low Speed operation (1.5 Mbps).

This chapter explains the operation modes.

57.1.2.1 Normal Mode

The OTG controller core can operate in Host mode and Device (Peripheral) mode. The Host-only controller core can operate in Host mode only.

Each USB controller core has its corresponding port, which can work in one or more interface modes.

NOTE

Each controller supports only the interface type listed below. Selecting a different interface type in the PORTSC.PTS field results in unpredictable behavior and may cause the system to hang.

- OTG1 port
 - This port supports on-chip UTMI transceiver only.
- OTG2 port
 - This port supports on-chip UTMI transceiver only.

NOTE

HSIC is an inter-chip interface that is optimized for circuit board layouts.

57.1.2.2 Low-Power Mode

Each USB controller core has a low-power mode (Suspend mode) to save power consumption.

As described in the USB 2.0 specification, the device can go into the Suspend state after it sees a constant Idle state on the upstream facing port. The OTG controller core enters Suspend mode after 3 ms of inactivity on the port when it is in Device Operation mode. Host controllers, including the OTG controller in Host mode, do not suspend automatically but can be placed in Suspend mode by software.

Either the local ARM platform or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication. For details about Suspend/Resume, see [USB Power Control](#).

57.2 External Signals

The table found here describes the external signals of USB.

57.3 Functional Description

These sections describe the functionality of the various building blocks of the USB.

57.3.1 USB 2.0 Controller Core 0

The USB 2.0 Controller 0 is an instantiation of an EHCI-compatible core which supports high-, full-, and low-speed operation.

In Host mode, this controller core supports high-, full-, and low-speed operation. In Device mode, it supports high- and full-speed operation.

57.3.1.1 Host Mode

The controller supports direct connection of .

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a USB 2.0 high speed hub has been implemented within the DMA and protocol engine blocks to support connection to full and low speed devices.

57.3.1.2 Peripheral (Device) Mode

- Up to eight bidirectional endpoints
- High/full-speed operation
- Support of HNP and SRP
- Remote wake-up capability

57.3.2 USB 2.0 Controller Core 1

USB 2.0 Controller Core 1 is an instantiation of EHCI-compatible core which supports High Speed / Full Speed / Low Speed operation with ULPI interface. It also supports High Speed operation with HSIC interface.

This USB core's signals connect directly to I/O pins (HSIC interface).

57.3.3 USB Power Control

The USB controller supports suspend and wake-up functionality.

The power control block allows for placing the transceiver in USB low power mode when USB bus is IDLE, and supports local and remote wake-up to bring the transceiver out of USB low power mode when needed. Additionally, the power control block can wake-up the ARM platform from core sleep mode by generating an interrupt.

57.3.3.1 Entering Low Power Suspend Mode

In Host operation mode, low power suspend mode is entered as follows:

1. Clear the ASE and PSE bits in USB_USBCMD, and wait until the AS and PS bits in USB_USBSTS become "0".
2. Set the "SUSPEND" bit in USB_PORTSC1.
3. Set the "PHCD" bit in USB_PORTSC1.
4. Set all PWD bits in USBPHYx_PWD
5. Set CLKGATE in USBPHYx_CTRL

NOTE

Step 3,4,5 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.

For device operation mode, low power suspend mode is entered as follows:

1. After Host drive is IDLE for 3ms, an SLI interrupt is issued (the "DCSUSPEND" or "SLI" bit in USB_USBSTS).
2. Set the "PHCD" bit on USB_PORTSC1
3. Set all PWD bits in USBPHYx_PWD
4. Set CLKGATE in USBPHYx_CTRL

NOTE

Step 2,3,4 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.

57.3.3.2 Wake-Up Events

The power control block monitors the USB bus when the USB core is in the USB suspend state.

Depending on whether the core is on Host or Device mode, a number of wake-up conditions are monitored. Upon detection of a wake-up condition, an interrupt (asynchronous) will be generated to ARM platform if the related wake-up interrupt enable bit is set.

USB wake-up interrupt also re-activates the ARM platform clocks if they were stopped during the suspend.

57.3.3.2.1 Host Mode Events

The host controller wakes up on the following events:

- Remote Wake-up Request

A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM/DP lines. The power control block sends a wake-up request to the USB core when a J-K transition on DM/DP line is detected.

- Wake-Up On Overcurrent

If Wake-Up On Overcurrent is enabled (WKOC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when an overcurrent event is detected.

- Wake-Up On Disconnect

If Wake-Up On Disconnect is enabled (WKDC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when a disconnection event is detected (J-SE0/K-SE0 transition on DM/DP line).

- Wake-Up On Connect

If a Wake-Up On Connect is enabled (WKCN bit in the USB core register PORTSC1 is set '1'), the power control sub-block sends a wake-up request to the USB core when the connection event is detected (SE0-J/SE0-K transition on DM/DP line).

For a detailed description of register bits WKOC, WKDC, WKCN, please see [Port Status & Control \(USB_nPORTSC1\)](#).

57.3.4 Interrupts

57.3.4.1 USB Core Interrupts

Each USB core uses one dedicated vector in the Interrupt Table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB Cores. Refer to the [Interrupt Enable Register \(USB_nUSBINTR\)](#) for details.

57.3.4.2 USB Wake-Up Interrupts

Each USB Core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but using the same vector as the corresponding USB controller cores interrupt.

These interrupts are generated by the Power Control blocks which run on the 32 KHz standby clock. The wake-up interrupt is designed to work even when the USB and ARM platform clocks are disabled, such that a wake-up condition on the USB bus can re-activate the ARM platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 KHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the ARM platform clock. The software should wait for at least three 32 KHz clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

57.4 USB Operation Model

This section describes the detailed application knowledge for OTG1 and OTG2 ports.

57.4.1 Register Interface

Configuration, control and status registers are divided into three categories, identification, capability and operational registers.

NOTE

USB controller registers support only DWORD (32-bit) access.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are dynamic control or status registers that may be read only, read/write, or read/write-to-clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

The following table describes the Interface register sets.

Table 57-1. Interface Register Sets

Offset	Register Set	Explanation
000h-07Ch	Identification Registers	Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.
100h-124h	Capability Registers	Capability registers specify the limits, restrictions, and capabilities of a host/device controller implementation. These values are used as parameters to the host/device controller driver.
080h-0FCh 140h-1FCh	Operational Registers	Operational registers are used by the system software to control and monitor the operational state of the host/device controller.

57.4.1.1 Configuration, Control and Status Register Set

The following table describes the Device/Host capability registers.

NOTE

Depending on implementation, "x" can have the following values: UOG1, UOG2.

Table 57-2. Device/Host Capability Registers

Offset	Size (Bytes)	Mnemonic	Register Name	Device Mode	Host Mode
000h	4	USB_x_ID	Identification Register	O	O
004h	4	USB_x_HWGENERAL	General Hardware Parameters	O	O
008h	4	USB_x_HWHOST	Host Hardware Parameters	X	O
00Ch	4	USB_x_HWDEVICE	Device Hardware Parameters	O	X

1B4h	4	USB_X_ENDPTFLUSH	Endpoint De-Initialization	O	X
1B8h	4	USB_X_ENDPTSTATUS	Endpoint Status	O	X
1BCh	4	USB_X_ENDPTCOMPLETE	Endpoint Complete	O	X
1C0	64	USB_X_ENDPTCTRL0	Endpoint Control Register 0-7	O	X

Table 57-2. Device/Host Capability Registers

Offset	Size (Bytes)	Mnemonic	Register Name	Device Mode	Host Mode
1C4		USB_x_ENDPTCTRL1			
...				
1DCh		USB_x_ENDPTCTRL7			

NOTE

"O" means the register is available in host/device operation mode;

"X" means the register is reserved in host/device operation mode

57.4.1.2 Identification Registers

Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.

57.4.1.3 OTG Operations**57.4.1.3.1 Register Bits**

In the previous section, the Register interface has behaviors described for device mode and behaviors described for host mode. However, for OTG operations it is necessary to perform tasks independent of the controller mode.

NOTE

The only way to transit the controller mode out of host or device mode is with the controller reset bit. Therefore, it is also necessary for the OTG tasks to be performed independent of a controller reset as well as independent of the controller mode.

The following figure shows the controller mode.

Figure 57-1. Controller Mode

To this end, listed below are the register bits that are used for OTG operations, which are independent of the controller mode and are also not affected by a write to the reset bit in the USBCMD register:

All Identification Registers

All Device/Host Capability Registers

57.4.2 Host Data Structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the Enhanced Host Controller (hardware).

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of a Periodic Schedule, Periodic Frame List, Asynchronous Schedule, Isochronous Transaction Descriptors, Split-transaction Isochronous Transfer Descriptors, Queue Heads, and Queue Element Transfer Descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) transfers for the host controller. The asynchronous list is the root for all the bulk and control transfers. Isochronous data streams are managed using Isochronous Transaction Descriptors. Isochronous split-transaction data streams are managed with Split-transaction Isochronous Transfer Descriptors. All Interrupt, Control, and Bulk data streams are managed via queue heads and Queue Element Transfer Descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI host controller spans a 4 K-page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

57.4.2.1 Periodic Frame List

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the `USB_PERIODICLISTBASE` address register and the `USB_FRINDEX` register.

The periodic schedule is based on an array of pointers called the Periodic Frame List.

The `USB_PERIODICLISTBASE` address register is combined with the `USB_FRINDEX` register to produce a memory pointer into the frame list. The Periodic Frame List implements a sliding window of work over time.

The following figure shows the organization of periodic schedule.

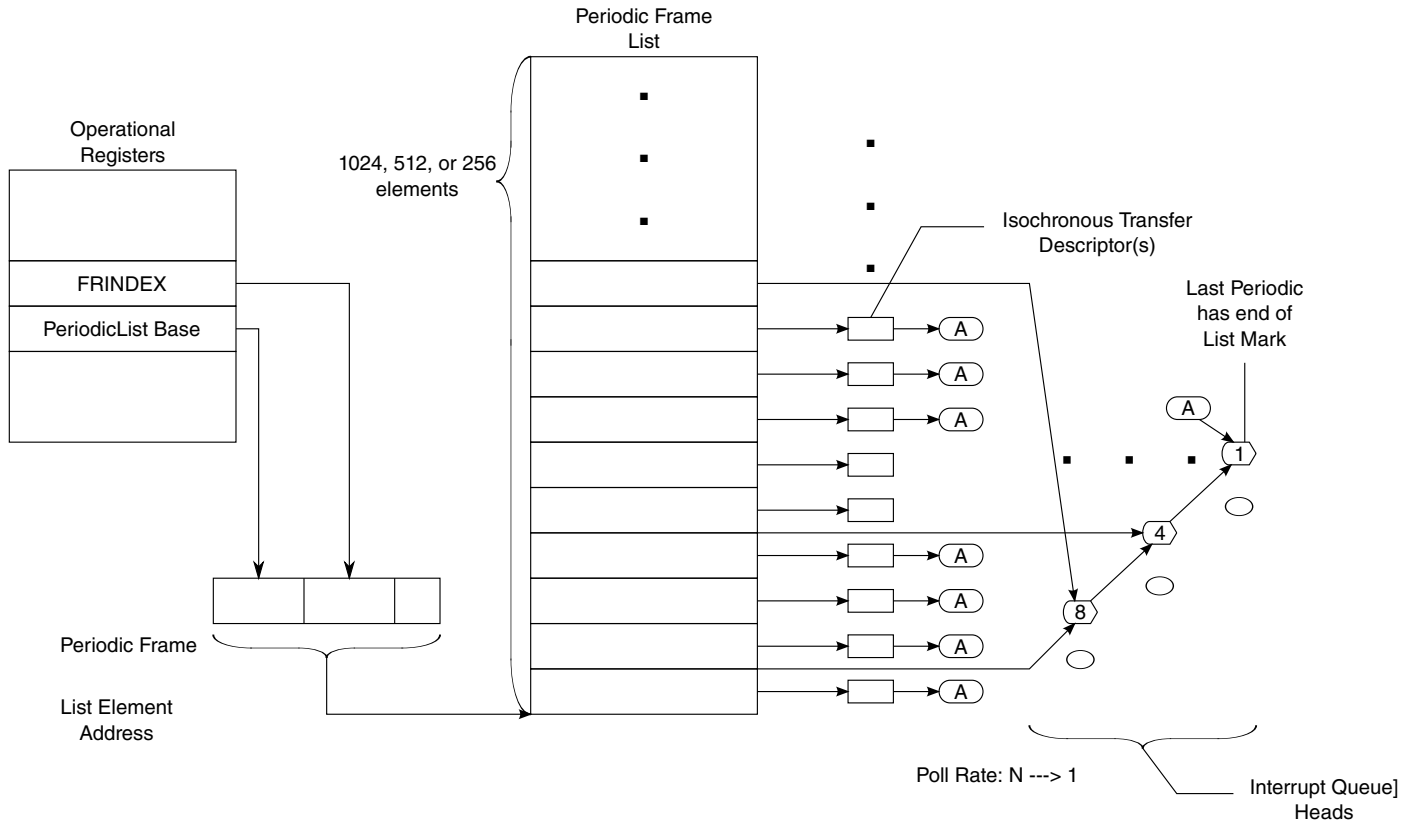

Figure 57-2. Periodic Schedule Organization

Split transaction Interrupt, Bulk and Control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4 K-page aligned array of Frame List Link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to system software via the USB_HCCPARAMS register. If non-programmable, the length is 1024 elements. If programmable, the length can be selected by system software as one of 256, 512, or 1024 elements. An implementation must support all three sizes. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into Frame List Size field in the USB_USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current micro-frame. The link pointers are aligned on DWord boundaries within the Frame List.

The table below illustrates the format of the Frame list element pointer.

Table 57-3. Format of Frame List Element Pointer

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	---	---	---	---	---	---	---	---	---	---	--

Table continues on the next page...

Table 57-3. Format of Frame List Element Pointer (continued)

Frame List Link Pointer	0	Typ	03-00H
-------------------------	---	-----	--------

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing.

The least significant bit is the T-Bit (bit 0). When this bit is set to a one, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field is used to indicate the exact type of data structure being referenced by this pointer. The value encodings are.

Table 57-4. Typ Field Value Definitions

Value	Meaning
00b	Isochronous Transfer Descriptor
01b	Queue Head
10b	Split Transaction Isochronous Transfer Descriptor.
11b	Frame Span Traversal Node.

57.4.2.2 Asynchronous List Queue Head Pointer

The Asynchronous Transfer List (based at the USB_ASYNC_LIST_ADDR register) is where all of the control and bulk transfers are managed.

Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty.

Figure 57-3. Asynchronous Schedule Organization

The Asynchronous list is a simple circular list of queue heads. The USB_ASYNCLISTADDR register is simply a pointer to the next queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

57.4.2.3 Isochronous (High-Speed) Transfer Descriptor (iTDD)

The format of an isochronous transfer descriptor is shown in the table below.

This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

Table 57-5. Isochronous Transaction Descriptor (iTDD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host Controller Read/Write

Host Controller Read Only

These fields may be modified by the host controller if the I/O field indicates an OUT.

57.4.2.3.1 Next Link Pointer

The first DWord of an iTD is a pointer to the next schedule data structure.

The following table describes the Next Schedule Element pointer field.

Table 57-6. Next Schedule Element Pointer

Bit	Description
31-5 Link Pointer (LP)	These bits correspond to memory address signals [31:5], respectively. This field points to another Isochronous Transaction Descriptor (iTID/siTID) or Queue Head (QH).
4-3	These bits are reserved and their value has no effect on operation. Software should initialize this field to zero.

Table continues on the next page...

Table 57-6. Next Schedule Element Pointer (continued)

Reserved	
2-1 QH/(s)iTD Select (Typ)	This field indicates to the Host Controller whether the item referenced is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0 Terminate (T)	1= Link Pointer field is not valid. 0= Link Pointer field is valid.

57.4.2.3.2 iTD Transaction Status and Control List

DWords 1 through 8 are eight slots of transaction control and status.

Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The PG and Transaction X Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list, to execute a transaction on the USB.

The following table describes iTD Transaction Status and Control fields.

Table 57-7. iTD Transaction Status and Control

Bit	Description
31-28 Status	This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:
Bit	Definition
31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.
30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.
29	Babble Detected. Set to one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.

Table continues on the next page...

Table 57-7. iTD Transaction Status and Control (continued)

Bit	Description
28	Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.
27-16 Transaction X Length	For an OUT, this field is the number of data bytes the host controller sends during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (0±zero length data, 1±one byte, 2±two bytes, etc.). The maximum value this field may contain is 0xC00 (3072).
15 Interrupt On Complete (IOC)	If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.
14-12 Page Select (PG)	These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.
11-0 Transaction X Offset	This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent PG field to produce the starting buffer address for this transaction.

57.4.2.3.3 iTD Buffer Page Pointer List (Plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4 K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous.

Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) * 1024 (maximum packet size) * 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Because each pointer is a 4 K aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

The tables below illustrate the field descriptions.

Table 57-8. iTD Buffer Pointer Page 0 (Plus)

Bit	Description
31-12 Buffer Pointer (Page 0)	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-8 Endpoint Number (Endpt)	This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.

Table continues on the next page...

Table 57-8. iTD Buffer Pointer Page 0 (Plus) (continued)

Bit	Description
7 Reserved	Bit reserved for future use and should be initialized by software to zero.
6-0 Device Address	This field selects the specific device serving as the data source or sink.

Table 57-9. iTD Buffer Pointer Page 1 (Plus)

Bit	Description
31-12 Buffer Pointer (Page 1)	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11 Direction (I/O)	0 = OUT; 1 = IN. This field encodes whether the high-speed transaction should use an IN or OUT PID.
10-0 Maximum Packet Size	This directly corresponds to the maximum packet size of the associated endpoint (<i>wMaxPacketSize</i>). This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (per micro-frame). This field is used with the <i>Multi</i> field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (400h). Any value larger yields undefined results.

Table 57-10. iTD Buffer Pointer Page 2 (Plus)

Bit	Description
31-12 Buffer Pointer	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-2 Reserved	This bit reserved for future use and should be set to zero.
1-0 Multi	This field is used to indicate to the host controller the number of transactions that should be executed per transaction description (per micro-frame). The valid values are: Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro- frame. 10b Two transactions to be issued for this endpoint per micro- frame. 11b Three transactions to be issued for this endpoint per micro- frame.

Table 57-11. iTD Buffer Pointer Page 3-6

Bit	Description
31-12 Buffer Pointer	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-0 Reserved	These bits reserved for future use and should be set to zero.

57.4.2.4 Split Transaction Isochronous Transfer Descriptor (siTD)

All Full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure. This data structure satisfies the operational requirements for managing the split transaction protocol.

The following table shows the Split Transaction Isochronous Transfer Descriptor (siTD).

Table 57-12. Split Transaction Isochronous Transfer Descriptor

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

Host Controller Read/Write

Host Controller Read Only

57.4.2.4.1 Next Link Pointer

DWord0 of a siTD is a pointer to the next schedule data structure.

The following table describes the Next Link Pointer fields.

Table 57-13. Next Link Pointer

Bit	Description
31-5	Next Link Pointer (LP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.

Table continues on the next page...

Table 57-13. Next Link Pointer (continued)

Bit	Description
4-3	Reserved. These bits must be written as zeros.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD/siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

57.4.2.4.2 siTD Endpoint Capabilities/Characteristics

DWords 1 and 2 specify static information about the full-speed endpoint, the addressing of the parent Companion Controller, and micro-frame scheduling control.

The tables below describe the Endpoint and transaction translator characteristics and micro-frame schedule control fields.

Table 57-14. Endpoint and Transaction Translator Characteristics

Bit	Description
31	Direction (I/O). 0 = OUT; 1 = IN. This field encodes whether the full-speed transaction should be an IN or OUT.
30-24	Port Number. This field is the port number of the recipient Transaction Translator.
23	Reserved. Bit reserved and should be set to zero.
22-16	Hub Address. This field holds the device address of the Companion Controllers' hub.
15-12	Reserved. Field reserved and should be set to zero.
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit is reserved for future use. It should be set to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

Table 57-15. Micro-frame Schedule Control

Bit	Description
31-16	Reserved. This field reserved for future use. It should be set to zero.
15-8	Split Completion Mask (mFrame C-Mask). This field (along with the <i>Active</i> and <i>SplitX-state</i> fields in the <i>Status</i> byte) is used to determine during which micro-frames the host controller should execute complete-split transactions. When the criteria for using this field is met, an all zeros value has undefined behavior. The host

Table continues on the next page...

Table 57-15. Micro-frame Schedule Control (continued)

Bit	Description
	controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the <i>mFrame C-Mask</i> field is a one, then this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Split Start Mask (<i>mFrame S-mask</i>). This field (along with the <i>Active</i> and <i>SplitX-state</i> fields in the <i>Status</i> byte) is used to determine during which micro-frames the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the <i>mFrame S-mask</i> field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

57.4.2.4.3 siTD Transfer State

DWords 3-6 are used to manage the state of the transfer.

The following table describes siTD transfer state fields.

Table 57-16. siTD Transfer Status and Control

Bit	Description
31	Interrupt On Complete (<i>ioc</i>). 0 = Do not interrupt when transaction is complete. 1 = Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it asserts a hardware interrupt at the next interrupt threshold.
30	Page Select (<i>P</i>). Used to indicate which data page pointer should be concatenated with the <i>CurrentOffset</i> field to construct a data buffer pointer (0 selects <i>Page 0</i> pointer and 1 selects <i>Page 1</i>). The host controller is not required to write this field back when the siTD is retired (<i>Active</i> bit transitioned from a one to a zero).
29-26	Reserved. This field reserved for future use and should be set to zero.
25-16	Total Bytes To Transfer. This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)
15-8	μ Frame Complete-split Progress Mask (<i>C-prog-Mask</i>). This field is used by the host controller to record which split-completes has been executed.
7-0: Status—This field records the status of the transaction executed by the host controller for this slot. It is a bit vector with the encoding shown in the following rows.	
7	Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.
6	ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.
5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overrun condition occurs, no action is necessary.
4	Babble Detected. Set to a one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.
3	Transaction Error (<i>XactErr</i>). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit is set only for IN transactions.
2	Missed Micro-Frame. The host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction.

Table continues on the next page...

Table 57-16. siTD Transfer Status and Control (continued)

Bit	Description
1	<p>Split Transaction State (SplitXstate). The bit encodings are:</p> <p>Value Meaning</p> <p>00b Do Start Split.</p> <p>This value directs the host controller to issue a Start split transaction to the endpoint when a match is encountered in the S-mask.</p> <p>01b Do Complete Split.</p> <p>This value directs the host controller to issue a Complete split transaction to the endpoint when a match is encountered in the C-mask.</p>
0	Reserved. Bit reserved for future use and should be set to zero.

57.4.2.4.4 siTD Buffer Pointer List (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4 K (page) aligned buffer pointers.

The least significant 12 bits of each DWord are used as additional transfer state. The following table describes the siTD buffer pointer fields.

Table 57-17. Buffer Page Pointer List (plus)

Bit	Description
31-12	Buffer Pointer List. Bits [31:12] of DWords 4 and 5 are 4 K page aligned physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field <i>P</i> (see siTD Transfer State) specifies the <i>current</i> active pointer.
Bits 11-0 (Page 0)	Current Offset—The 12 least significant bits of the Page 0 pointer are the current byte offset for the current page pointer (as selected with the page indicator bit (<i>P</i> field)). The host controller is not required to write this field back when the siTD is retired (<i>Active</i> bit transitioned from a one to a zero).
Bits 11-0 (Page 1)—The least significant bits of the Page 1 pointer are split into three subfields as shown in the following rows.	
11-5 (Page 1)	Reserved
4-3 (Page 1)	<p>Transaction position (TP). This field is used with T-count to determine whether to send <i>all</i>, <i>first</i>, <i>middle</i>, or <i>last</i> with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are:</p> <p>Value Meaning</p> <p>00b All. The entire full-speed transaction data payload is in this transaction (that is, less than or equal to 188 bytes).</p> <p>01b Begin. This is the first data payload for a full-speed that is greater than 188 bytes.</p> <p>10B Mid. This is the <i>middle</i> payload for a full-speed OUT transaction that is larger than 188 bytes.</p>

Table continues on the next page...

Table 57-17. Buffer Page Pointer List (plus) (continued)

Bit	Description
	11b End. This is the <i>last</i> payload for a full-speed OUT transaction that was larger than 188 bytes.
2-0 (Page 1)	Transaction count (T-Count). Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

57.4.2.4.5 siTD Back Link Pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD, and it cannot reference any other schedule data structure.

The following table describes the siTD back link pointer fields.

Table 57-18. siTD Back Link Pointer

Bit	Description
31-5	siTD Back Pointer. This field is a physical memory pointer to a siTD.
4-1	Reserved. This field is reserved for future use. It should be set to zero.
0	Terminate (T). 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.

57.4.2.5 Queue element transfer descriptor (qTD)

This data structure is only used with a queue head. It describes one or more USB transactions to transfer up to 20480 (5*4096) bytes.

The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers.

It is 32 bytes and must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary; however, for optimal utilization of on-chip busses it is recommended to align the buffers on a 32-byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a queue head.

The following table shows the queue element transfer descriptor data structure.

Table 57-19. Queue element transfer descriptor data structure

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

1. 08-0F: Transfer Results

Host Controller Read/Write

Host Controller Read Only

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

57.4.2.5.1 Next qTD Pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor.

The following table describes Next qTD pointer fields.

Table 57-20. qTD Next Element Transfer Pointer (DWord 0)

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.
4-1	Reserved

Table continues on the next page...

Table 57-20. qTD Next Element Transfer Pointer (DWord 0) (continued)

0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.
---	--

57.4.2.5.2 Alternate Next qTD Pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next transfer descriptor on short packet. To be more explicit the host controller always uses this pointer when the current qTD is retired due to short packet.

The following table describes the TD Alternate Next Element Transfer Pointer field descriptions.

Table 57-21. TD Alternate Next Element Transfer Pointer (DWord 1)

Bit	Description
31-5	Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

57.4.2.5.3 qTD Token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

NOTE

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

The following table describes the TD Token fields.

Table 57-22. TD Token (DWord 2)

Bit	Description
31 Data Toggle	This is the data toggle sequence bit. The use of this bit depends on the setting of the <i>Data Toggle Control</i> bit in the queue head.

Table continues on the next page...

Table 57-22. TD Token (DWord 2) (continued)

Bit	Description						
30-16 Total Bytes to Transfer	<p>This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 * 4K (5000H). This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that <i>Total Bytes To Transfer</i> be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction is always less than QHD.Maximum Packet Length.</p> <p>Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16 K(4000H).</p>						
15 Interrupt On Complete (IOC)	If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.						
14-12 Current Page (C_Page)	This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0H to 4H. The host controller is not required to write this field back when the qTD is retired.						
11-10 Error Counter (CERR)	<p>This field is a 2-bit down counter that keeps track of the number of consecutive Errors detected while executing this qTD. If this field is programmed with a non-zero value during set-up, the Host Controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the <i>Halted</i> bit to a one, and error status bit for the error that caused <i>CERR</i> to decrement to zero. An interrupt is generated if the <i>USB Error Interrupt Enable</i> bit in the USBINTR register is set to a one. If HCD programs this field to zero during set-up, the Host Controller does not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD.</p> <p>Transaction Error - Decrement Data Buffer Error - No Decrement³ Stalled - No Decrement¹ Babble Detected - No Decrement¹ No Error - No Decrement²</p> <table border="1"> <thead> <tr> <th>Error</th> <th>Decrement Counter</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented</td> </tr> <tr> <td>2</td> <td>If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and <i>PIDCode</i> indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset <i>CERR</i> to extend the total number of errors for this transaction. For example, <i>CERR</i> should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.</td> </tr> </tbody> </table> <p>See Split Transaction Interrupt for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See Asynchronous - Do Complete Split for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the <i>PIDCode</i> indicates a SETUP.</p>	Error	Decrement Counter	1	Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented	2	If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and <i>PIDCode</i> indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset <i>CERR</i> to extend the total number of errors for this transaction. For example, <i>CERR</i> should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.
Error	Decrement Counter						
1	Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented						
2	If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and <i>PIDCode</i> indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset <i>CERR</i> to extend the total number of errors for this transaction. For example, <i>CERR</i> should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.						

Table continues on the next page...

Table 57-22. TD Token (DWord 2) (continued)

Bit	Description
3	Data buffer errors are host problems. They don't count against the device's retries. NOTE: Software must not program CERR to a value of zero when the EPS field is programmed with a value indicating a Full- or Low-speed device. This combination could result in undefined behavior.
9-8 PID Code	This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. Encodings are:
00b	OUT Token generates token (E1H)
01b	IN Token generates token (69H)
10b	SETUP Token generates token (2DH) (undefined if endpoint is an interrupt, the queue head is non-zero) transfer type, for example, μ Frame S-mask field in.
11b	Reserved
7-0 Status	This field is used by the Host Controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. The bit encodings are:
Bit	Status Field Description
7	Active. Set to one by software to enable the execution of transactions by the Host Controller.
6	Halted. Set to one by the Host Controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set to a one, the Active bit is also set to zero.
5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overflow) or is unable to supply data fast enough during transmission (under run). If an overflow condition occurs, the Host Controller forces a timeout condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
4	Babble Detected. Set to a one by the Host Controller during status update when "babble" is detected during the transaction. In addition to setting this bit, the Host Controller also sets the <i>Halted</i> bit to a one. Because "babble" is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
2	Missed Micro-Frame. This bit is ignored unless the <i>QH.EPS</i> field indicates a full- or low-speed endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
1	Split Transaction State (SplitXstate). This bit is ignored by the host controller unless the <i>QH.EPS</i> field indicates a full- or low-speed endpoint. When a Full- or Low-speed device, the host controller uses this bit to track the state of the split-

Table continues on the next page...

Table 57-22. TD Token (DWord 2) (continued)

Bit	Description
	<p>transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the endpoint is in the periodic or asynchronous schedule. The bit encodings are:</p> <p>Value Meaning</p> <p>0b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint.</p> <p>1b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint.</p>
0	<p>Ping State (P)/ERR. If the <i>QH.EPS</i> field indicates a High-speed device and the <i>PID_Code</i> indicates an OUT endpoint, then this is the state bit for the Ping protocol. The bit encodings are:</p> <p>Value Meaning</p> <p>0b Do OUT. This value directs the host controller to issue an OUT PID to the endpoint.</p> <p>1b Do Ping. This value directs the host controller to issue a PING PID to the endpoint.</p> <p>If the <i>QH.EPS</i> field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.</p>

57.4.2.5.4 qTD Buffer Page Pointer List

The last five DWords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes Current Offset field to the starting offset into the current page, where current page is selected through the value in the *C_Page* field.

The following table describes the qTD Buffer Pointer(s) (DWords 3-7) fields.

Table 57-23. qTD Buffer Pointer(s) (DWords 3-7)

Bit	Description
31-12	<p>Buffer Pointer List. Each element in the list is a 4 K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4 K page. The field <i>C_Page</i> specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using <i>C_Page</i> (similar to an array index to select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment <i>C_Page</i> and advance to the next buffer pointer in the list, and conclude the transaction through the new buffer pointer.</p>
11-0	<p>Current Offset (Reserved). This field is reserved in all pointers except the first one (for example Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by <i>C_Page</i>). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zero.</p>

57.4.2.6 Queue Head

The table located in this section shows the Queue Head structure layout.

The following table shows the queue head structure layout.

Table 57-24. Queue Head Structure Layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

3. 10-2F: Transfer overlay.
4. 14-27: Transfer results.

Host Controller Read/Write

Host Controller Read Only

57.4.2.6.1 Queue Head Horizontal Link Pointer

The first DWord of a Queue Head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

The following table describes the Queue head DWord 0 fields.

Table 57-25. Queue Head DWord 0

Bit	Description
31-5	Queue Head Horizontal Link Pointer (QHLP). This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD Select (Typ). This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

57.4.2.6.2 Queue Head Endpoint Capabilities/Characteristics

The second and third DWords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint.

There are three types of information in this region:

- **Endpoint Characteristics.** These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.
- **Endpoint Capabilities.** These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- **Split Transaction Characteristics.** This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

The following table describes the Endpoint characteristics: Queue head DWord 1 fields.

Table 57-26. Endpoint Characteristics: Queue Head DWord 1

Bit	Description	
31-28	Nak Count Reload (RL). This field contains a value, which is used by the host controller to reload the Nak Counter field.	
27	Control Endpoint Flag (C). If the <i>QH.EPS</i> field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to zero.	
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (<i>wMaxPacketSize</i>). The maximum value this field may contain is 0x400 (1024).	
15	Head of Reclamation List Flag (H). This bit is set by System Software to mark a queue head as being the head of the reclamation list.	
14	Data Toggle Control (DTC). This bit specifies where the host controller should get the initial data toggle on an overlay transition. 0b Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head. 1b Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD.	
13-12	Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are:	
	Value	Meaning
	00b	Full-Speed (12 Mbits/sec)
	01b	Low-Speed (1.5 Mbits/sec)
	10b	High-Speed (480 Mbits/sec)
	11b	Reserved
This field must not be modified by the host controller.		
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.	
7	Inactivate on Next Transaction (I). This bit is used by system software to request that the host controller set the Active bit to zero. See Rebalancing the periodic schedule , for full operational details. This field is only valid when the queue head is in the Periodic Schedule and the <i>EPS</i> field indicates a Full or Low-speed endpoint. Setting this bit to one when the queue head is in the Asynchronous Schedule or the <i>EPS</i> field indicates a high-speed device yields undefined results.	
6-0	Device Address. This field selects the specific device serving as the data source or sink.	

The table below describes the Endpoint capabilities: Queue head DWord 2 field descriptions.

Table 57-27. Endpoint Capabilities: Queue Head DWord 2

Bit	Description
31-30	High-Bandwidth Pipe Multiplier (Mult). This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). The valid values are: Value Meaning

Table continues on the next page...

Table 57-27. Endpoint Capabilities: Queue Head DWord 2 (continued)

	<p>00b Reserved. A zero in this field yields undefined results.</p> <p>01b One transaction to be issued for this endpoint per micro-frame.</p> <p>10b Two transactions to be issued for this endpoint per micro-frame.</p> <p>11b Three transactions to be issued for this endpoint per micro-frame.</p>
29-23	Port Number. This field is ignored by the host controller unless the <i>EPS</i> field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address <i>Hub Addr</i> below), below which the full- or low-speed device associated with this endpoint is attached. This information is used in the split-transaction protocol.
22-16	Hub Addr. This field is ignored by the host controller unless the <i>EPS</i> field indicates a full- or low-speed device. The value is the USB device address of the USB 2.0 Hub below which the full- or low-speed device associated with this endpoint is attached. This field is used in the split-transaction protocol.
15-8	Split Completion Mask (μ Frame C-Mask). This field is ignored by the host controller unless the <i>EPS</i> field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the <i>Active</i> and <i>SplitX-state</i> fields) is used to determine during which micro-frames the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the μ Frame C- Mask field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Interrupt Schedule Mask (μ Frame S-mask). This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the μ Frame S-mask field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the <i>EPS</i> field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the <i>PID_Code</i> field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the <i>EPS</i> field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.

57.4.2.6.3 Transfer Overlay-Queue Head

The nine DWords in this area represent a transaction working space for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the Queue Head Horizontal Link Pointer to the next queue head. The host controller will never follow the Next Transfer Queue Element or Alternate Queue Element pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

The following table describes the current qTD link pointer field descriptions.

Table 57-28. Current qTD Link Pointer

Bit	Description
31-5	Current Element Transaction Descriptor Link Pointer. This field contains the address Of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4-0	Reserved (R). These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves as execution cache for the transfer.

The table below describes the Host-controller rules for bits in overlay.

Table 57-29. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9)

DWord	Bit	Description
5	4-1	Nak Counter (NakCnt) μ RW. This field is a counter the host controller decrements whenever a transaction for the endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from <i>RL</i> before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from <i>RL</i> during an overlay.
6	31	Data Toggle. The <i>Data Toggle Control</i> controls whether the host controller preserves this bit when an overlay operation is performed.
6	15	Interrupt On Complete (IOC). The IOC control bit is always inherited from the source qTD when the overlay operation is performed.
6	11-10	Error Counter (C_ERR). This two-bit field is copied from the qTD during the overlay and written back during queue advancement.
6	0	Ping State (P)/ERR. If the <i>EPS</i> field indicates a high-speed endpoint, then this field should be preserved during the overlay operation.
8	7-0	Split-transaction Complete-split Progress (C-prog-mask). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4-0	Split-transaction Frame Tag (Frame Tag). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	11-5	S-bytes. Software must ensure that the <i>S-bytes</i> field in a <i>qTD</i> is zero before activating the <i>qTD</i> . This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.

57.4.2.7 Periodic Frame Span Traversal Node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary.

See [Host Controller Operational Model for FSTNs](#) for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose USB_HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use yields undefined results.

Table 57-30. Frame Span Traversal Node Structure Layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr
Normal Path Link Pointer																												0	Typ	T	03-00	
Back Path Link Pointer																												0	Typ ¹	T	07-04	

1. Must be set to indicate a queue head

Host Controller Read/Write

Host Controller Read Only

57.4.2.7.1 FSTN Normal Path Pointer

The first DWord of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

The following table describes the FSTN normal path pointer fields.

Table 57-31. FSTN Normal Path Pointer Field Descriptions

Bit	Description
31-5	Normal Path Link Pointer (NPLP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD/FSTN Select (Typ). This field indicates to the Host Controller whether the item referenced is a iTD/siTD, a QH or an FSTN. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (Frame Span Traversal Node)
0	Terminate (T). 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

57.4.2.7.2 FSTN Back Path Link Pointer

The second DWord of an FTSN node contains a link pointer to a queue head.

If the T-bit in this pointer is zero, then this FSTN is a Save-Place indicator. Its Typ field must be set by software to indicate the target data structure is a queue head. If the T-bit in this pointer is set to one, then this FSTN is the Restore indicator. When the T-bit is one, the host controller ignores the Typ field.

The following table describes the FSTN back path link pointer fields.

Table 57-32. FSTN Back Path Link Pointer Field Descriptions

Bit	Description
31-5	Back Path Link Pointer (BPLP). This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	Typ. Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.
0	Terminate (T). 1=Link Pointer field is not valid (that is the host controller must not use bits [31:5] as a valid memory address). This value also indicates that this FSTN is a Restore indicator. 0=Link Pointer is valid (that is the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.

57.4.3 Host Operational Model

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (generally referred to as system software).

Each significant operational feature of the EHCI host controller is discussed in a separate section. Each section presents the operational model requirements for the host controller hardware. Where appropriate, recommended system software operational models for features are also presented.

57.4.3.1 Host Controller Initialization

After initial power-on or HCRreset (hardware or through HCRreset bit in the USB_USBCMD register), all of the operational registers are at their default values. After a hardware reset, only the operational registers not contained in the Auxiliary power well are at their default values.

The following table describes the default values of operational registers.

Table 57-33. Default Values of Operational Register Space

Operational Register	Default Value (after Reset)
USB_USBCMD	00080000h (00080B00h, if <i>Asynchronous Schedule Park Capability is one</i>)
USB_USBSTS	00001000h
USB_USBINTR	00000000h
USB_FRINDEX	00000000h
USB_CTRLDSSEGMENT	00000000h
USB_PERIODICLISTBASE	Undefined
USB_ASYNCLISTADDR	Undefined
USB_CONFIGFLAG	00000000h
USB_PORTSC1	00002000h (w/ <i>PPC</i> set to one); 00003000h (w/ <i>PPC</i> set to zero)

To initialize the host controller, software should perform the following steps:

- Write the appropriate value to the USB_USBINTR register to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to the USB_PERIODICLIST BASE register. If no work items are in the periodic schedule, all elements of the Periodic Frame List should have their T-Bits set to one.
- Write the USB_USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller ON through setting the Run/Stop bit.

At this point, the host controller is up and running and the port registers begin reporting device connects, and so on. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled ports, but the schedules have not enabled. To communicate with devices through the asynchronous schedule, system software must write the USB_ASYNCLISTADDR register with the address of a control or bulk queue head. Software must then enable the asynchronous schedule by writing one to the Asynchronous Schedule Enable bit in the USB_USBCMD register. To communicate with devices through the periodic schedule, system software must enable the periodic schedule by writing one to the Periodic Schedule Enable bit in the USB_USBCMD register.

NOTE

The schedules can be turned on before the first port is reset (and enabled).

When the USB_USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

57.4.3.2 Port Routing and Control

The EHCI specification defines that a USB 2.0 Host controller is comprised of one high-speed host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion host controllers.

Companion host controllers (cHCs) may be implementations of either Universal or Open host controller specifications. This configuration is used to deliver the required full USB 2.0-defined port capability; for example, Low-, Full-, and High-speed capability for every port.

NOTE

The USB controllers do not require nor support companion controllers to support Full and Low Speed device. Full and Low Speed devices are supported within the USB controller by emulating the functionality of a high-speed HUB. Therefore, no port routing is present in the controller. Please refer to [Embedded Transaction Translator Function](#) for details.

The following figure illustrates a simple block diagram of the port routing logic and its relationship to the high-speed and companion host controllers within a USB 2.0 host controller.

Figure 57-4. Example USB 2.0 Host Controller Port Routing Block Diagram

There exists one transceiver per physical port and each host controller block has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each companion host controller has only the port control and status registers it is required to operate. Either the EHCI host controller or one companion host controller controls each transceiver. Routing logic lies between the transceiver, the port status and control registers.¹

The port routing logic is controlled from signals originating in the EHCI host controller. The EHCI host controller has a global routing policy control field and per-port ownership control fields. The Configured Flag (CF) bit is the global routing policy control. At power-on or reset, the default routing policy is to the companion controllers (if they exist). If the system does not include a driver for the EHCI host controller and the host controller includes Companion Controllers, then the ports still work in Full- and Low-speed mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the companion host controllers' port registers do not see a connect indication from the transceiver. Similarly, when a companion host controller owns a port, the EHCI controller's port registers do not see a connect indication

1. The routing logic should not be implemented in the 480 MHz clock domain of the transceiver.

from the transceiver. The details on the rules for the port routing logic are described in the following sections. The USB 2.0 host controller must be implemented as a multi-function PCI device if the implementation includes companion controllers. The companion host controllers' function numbers must be less than the EHCI host controller function number. The EHCI host controller must be a larger function number with respect to the companion host controllers associated with this EHCI host controller. If a PCI device implementation contains only an EHCI controller (that is no companion controllers or other PCI functions), then the EHCI host controller must be function zero, in accordance with the PCI Specification. The N_CC field in the Structural Parameter register (HCSPARAMS) indicates whether the controller implementation includes companion host controllers. When N_CC has a non-zero value there exists companion host controllers. If N_CC has a value of zero, then the host controller implementation does not include companion host controllers. If the host controller root ports are exposed to attachment of full- or low-speed devices, the ports always fails the high-speed chirp during reset and the ports are not enabled. System software can notify the user of the illegal condition. This type of implementation requires a USB 2.0 hub be connected to a root port to provide full and low-speed device connectivity.

System software uses information in the host controller capability registers to determine how the ports are routed to the companion host controllers. See [Host Controller Structural Parameters \(USB_nHCSPARAMS\)](#)

57.4.3.2.1 Port Routing Control through EHCI Configured (CF) Bit

Each port in the USB 2.0 host controller are routed either to a single companion host controller or to the EHCI host controller.

The port routing logic is controlled by two mechanisms in the EHCI HC: a host controller global flag and per-port control. The Configured Flag (CF) bit, is used to globally set the policy of the routing logic. Each port register has a Port Owner control bit which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever the CF bit transitions from zero to one (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all Port Owner bits go to zero). While the CF-bit is one, the EHCI Driver controls individual ports' routing through the Port Owner control bit. Likewise, whenever the CF bit transitions from one to zero (as a result of Aux power application, HCRESET, or software writing zero to CF-bit), the port routing unconditionally routes all of the port registers to the appropriate companion HC. The default value for the EHCI HC's CF bit (after Aux power application or HCRESET) is zero.

The *view* of the port depends on the current owner. A Universal or Open companion host controller will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI host controllers are not visible to companion host controllers.

The following table summarizes the default routing for all the ports, based on the value of the EHCI HC's CF bit.

Table 57-34. Default Port Routing Depending on EHCI HC CF Bit

HS CF Bit	Default Port Ownership	Explanation
0B	Companion HCs	The companion host controllers own the ports and only Full- and Low-speed devices are supported in the system. The exact port assignments are implementation dependent. The ports behave only as Full- and Low-speed ports in this configuration
1B	EHCI HC	The EHCI host controller has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs' port status and control registers when the port owner is the EHCI HC. The EHCI HC has access to the additional port status and control bits defined in this specification (see Port Status & Control (USB_nPORTSC1)). The EHCI HC can temporarily release control of the port to a companion HC by setting the <i>PortOwner</i> bit in the PORTSC1 register to one.

57.4.3.2.2 Port Routing Control through PortOwner and Disconnect Event

Manipulating the port routing through the CF-bit is an extreme process and not intended to be used during normal operation.

The normal mode of port ownership transferal is on the granularity of individual ports using the Port Owner bit in the EHCI HC's USB_PORTSC1 register (for hand-offs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI *CF-bit* is set to one), the typical port enumeration sequence proceeds as illustrated below:

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and

identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.

- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the LineStatus bits in the USB_PORTSC1 register. If they indicate the attached device is a full-speed device (for example, D+ is asserted), then the EHCI Driver sets the PortReset control bit to one (and sets the PortEnable bit to zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing zero to the port reset bit. The reset process is actually complete when software reads zero in the PortReset bit. The EHCI Driver checks the PortOwner bit in the USB_PORTSC1 register. If set to one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.
- At the time the EHCI Driver receives the port reset and enable request the LineStatus bits might indicate a low-speed device. Additionally, when the port reset process is complete, the PortEnable field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the USB_PORTSC1 register to one to release port ownership to a companion host controller.
- When the EHCI Driver sets PortOwner bit to one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The EHCI USB_PORTSC1 register observes and reports a disconnect event through the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to one, a connect change set to one and a connect status set to zero. This information is derived directly from the EHCI port register. This allows the hub driver to assume the device was disconnected during reset. It acknowledges the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's CF-bit transitions from 1b to 0b). When a disconnect occurs, the disconnect event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects is detected by the EHCI port register and the process repeats.

57.4.3.2.3 Example Port Routing State Machine

The following figure illustrates an example of how the port ownership should be managed. The following sections describe the entry conditions to each state.

Figure 57-5. Port Owner Handoff State Machine

57.4.3.2.3.1 EHCI HC Owner

Entry to this state occurs when one of the following events occur:

- When the EHCI HC's Configure Flag (CF) bit in the USB_CONFIGFLAG register transitions from zero to one. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.
- When the port is owned by a companion HC and the device is disconnected from the port. The EHCI port routing control logic is notified of the disconnect, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver acknowledges the disconnect by setting the connect status change bit to zero. This allows the companion HC's driver to interact with the port completely through the disconnect process.
- When system software writes zero to the PortOwner bit in the USB_PORTSC1 register. This allows software to take ownership of a port from a companion host controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.

57.4.3.2.3.2 Companion HC Owner

Entry to this state occurs whenever one of the following events occur:

- When the PortOwner field transitions from zero to one.
- When the HS-mode HC's Configure Flag (CF) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

57.4.3.2.4 Port Power

The Port Power Control (PPC) bit in the USB_HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (see [Host Controller Structural Parameters \(USB_nHCSPARAMS\)](#)).

When this bit is zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the *PPC* bit is one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is referred to in this discussion as PortPowerOutputEnable (PPE). PPE is controlled based on the state of the combination bits PPC bit, EHCI Configured (CF)-bit and individual Port Power (PP) bits.

The following table describes the summary behavioral model.

Table 57-35. Port Power Enable Control Rules

CF	CHC ¹ (PP)	EHC ² (PP)	Owner	PPE ³	Description
0	0	X	CHC	0	When the EHCI controller is not configured, the port is owned by the companion host controller. When the companion HC's port power select is off, then the port power is off.
0	1	X	CHC	1	Similar to previous entry. When the companion HC's port power select is on, then the port power is on.
1	0	0	CHC	0	Port owner has port power turned off, the power to port is off.
1	0	0	EHC	0	Port owner has port power turned off, the power to port is off.
1	0	1	EHC	1	Port owner has port power on, so power to port is on.
1	0	1	CHC	1	If either HC has port power turned on, the power to the port is on.

Table continues on the next page...

Table 57-35. Port Power Enable Control Rules (continued)

1	1	0	EHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	EHC	1	Port owner has port power on, so power to port is on.

1. CHC (Companion Host Controller).
2. EHC (EHCI Host Controller).
3. PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists).

57.4.3.2.5 Port Reporting Over-Current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI USB_PORTSC1 register has an over-current status and over-current change bit.

The functionality of these bits are specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document.

The over-current condition effects the following bits in the USB_PORTSC1 register on the EHCI port:

- Over-current Active bits are set to one. When the over-current condition goes away, the Over-current Active bit transitions from one to zero.
- Over-current Change bits are set to one. On every transition of the Over-current Active bit the host controller sets the Over-current Change bit to one. Software sets the Over-current Change bit to zero by writing one to this bit.
- Port Enabled/Disabled bit is set to zero. When this change bit gets set to one, then the Port Change Detect bit in the USB_USBSTS register is set to one.
- Port Power (PP) bits may optionally be set to zero. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to limit the current and leave power applied. When the Over-current Change bit transitions from zero to one, the host controller also sets the Port Change Detect bit in the USB_USBSTS register to one. In addition, if the Port Change Interrupt Enable bit in the USB_USBINTR register is one, then the host controller issues an interrupt to the system. Refer to [Table 57-36](#) for summary behavior for over-current detection

when the host controller is halted (suspended from a device component point of view).

57.4.3.3 Suspend/Resume-Host Operational Model

The EHCI host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub.

Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely through software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wake-up events. The classes of wake-up events are:

- Remote-wake-up enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake-up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the USB_PORTSC1 registers.

Selective suspend is a feature supported by every USB_PORTSC1 register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the Run/Stop bit in the USB_USBCMD register to zero. The EHCI sub-block can then be placed into a lower device state through the PCI power management interface (see Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. <http://www.intel.com>).

When a wake event occurs, the system resumes operation and system software eventually set the Run/Stop bit to one and resume the suspended ports. Software must not set the Run/Stop bit to one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the ARM platform is restarted. So, by definition, if software is running, clocks in the system are stable and the Run/Stop bit in the USB_USBCMD register can be set to one. Minimum system software delays are also defined in the PCI Power Management Specification. Refer to PCI Power Management Specification for more information.

57.4.3.3.1 Port Suspend/Resume

System software places individual ports into suspend mode by writing one into the appropriate USB_PORTSC1 Suspend bit. Software must only set the Suspend bit when the port is in the enabled state (Port Enabled bit is one) and the EHCI is the port owner (PortOwner bit is zero).

The host controller may evaluate the Suspend bit immediately or wait until a micro-frame or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several micro-frames of activity on the port until the host controller evaluates the Suspend bit. The host controller must evaluate the Suspend bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing one to the Force Port Resume bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see [Port Status & Control \(USB_nPORTSC1\)](#)). If system software sets Force Port Resume bit to one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 ms after a port indicates that it is suspended (Suspend bit is one) before initiating a port resume through the Force Port Resume bit. When Force Port Resume bit is one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 ms) then sets the Force Port Resume bit to zero. When the host controller receives the write to transition Force Port Resume to zero, it completes the resume sequence as defined in the USB specification, and sets both the Force Port Resume and Suspend bits to zero. Software-initiated port resumes do not affect the Port Change Detect bit in the USB_USBSTS register nor do they cause an interrupt if the Port Change Interrupt Enable bit in the USB_USBINTR register is one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100 μ sec. The port's Force Port Resume bit is set to one and the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit in the USB_USBINTR register is one the host controller issues a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 ms), then terminates the resume sequence by writing zero to the Force Port Resume bit in the port. The host controller receives the write of zero to Force Port Resume, terminates the resume sequence and sets Force Port Resume and Suspend port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the USB_PORTSC1 register and observing that the Suspend and Force Port Resume bits are zero. Software must ensure that the host controller is running (that is HCHalted bit in the USB_USBSTS register is zero), before terminating a resume by writing zero to a

port's Force Port Resume bit. If HCHalted is one when Force Port Resume is set to zero, then SOFs do not occur down the enabled port and the device returns to suspend mode in a maximum of 10 msec.

The table below summarizes the wake-up events. Whenever a resume event is detected, the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit is one in the USB_USBINTR register, the host controller generates an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the Port Change Detect status bit in the USB_USBSTS register.

Table 57-36. Behavior During Wake-up Events

Port Status and Signaling Type	Signaled Port Response	Device State	
		D0	Not D0
Port disabled, resume K-State received	No Effect	N/A	N/A
Port suspended, resume K-State received	Resume reflected downstream on signaled port. Force Port Resume status bit in USB_PORTSC1 register is set to one. Port Change Detect bit in USB_USBSTS register set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is one. A disconnect is detected.	Depending in the initial port state, the USB_PORTSC1 Connected Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is zero. A disconnect is detected.	Depending on the initial port state, the USB_PORTSC1 Connect and Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is not connected and the port's WKCNNT_E bit is one. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is not connected and the port's WKCNNT_E bit is zero. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is connected and the port's WKOC_E bit is one. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one	[1], [2]	[2]
Port is connected and the port's WKOC_E bit is zero. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]

[1] Hardware interrupt issued if Port Change Interrupt Enable bit in the USB_USBINTR register is one.

[2] PME# asserted if enabled (Note: PME Status must always be set to one).

[3] PME# not asserted.

57.4.3.4 Schedule Traversal Rules

The host controller executes transactions for devices using a simple, shared-memory schedule.

The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the USB_PERIODICLISTBASE register (see [Frame List Base Address \(USB_nPERIODICLISTBASE\)](#))/ [Device Address \(USB_nDEVICEADDR\)](#)). The USB_PERIODICLISTBASE register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in [Host Data Structures](#). In each micro-frame, if the periodic schedule is enabled (see [Periodic scheduling threshold](#)) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It only executes from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the USB_PERIODICLISTBASE and the USB_FRINDEX registers (see the following figure). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a next link pointer of a schedule data structure having its T-bit set to one. When the host controller encounters a T-Bit set to one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic schedule and transitions immediately to traversing the asynchronous schedule. After the transition, the host controller executes from the asynchronous schedule until the end of the micro-frame.

The following figure illustrates the derivation of pointer into frame list array.

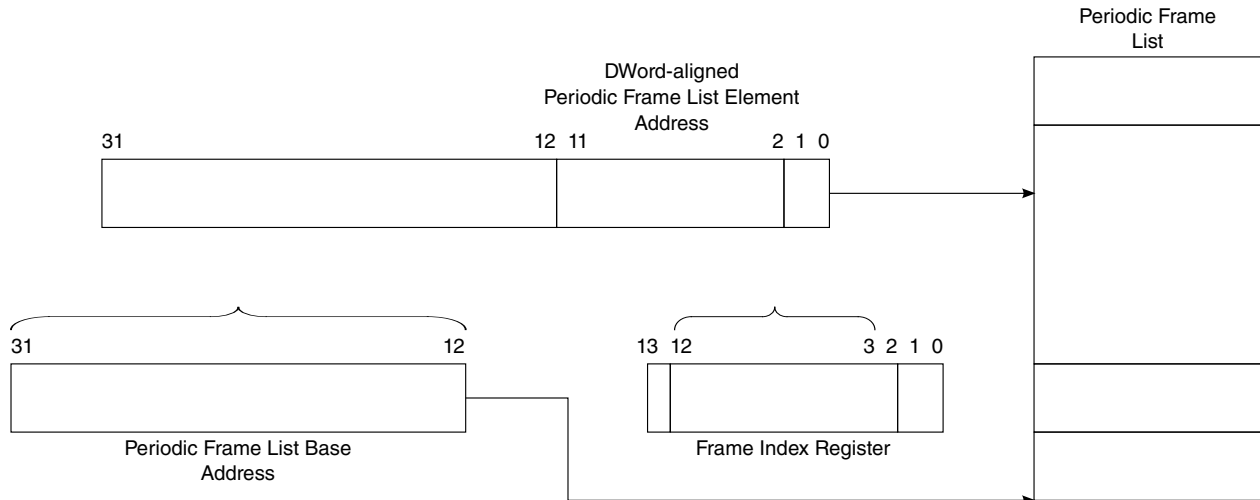

Figure 57-6. Derivation of Pointer into Frame List Array

When the host controller determines that it is the time to execute from the asynchronous list, it uses the operational register `USB_ASYNC_LIST_ADDR` to access the asynchronous schedule, see the figure below.

Figure 57-7. General Format of Asynchronous Schedule List

The `USB_ASYNC_LIST_ADDR` register contains a physical memory pointer to the next queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the `USB_ASYNC_LIST_ADDR` register. Software must set queue head horizontal pointer T-bits to zero for queue heads in the asynchronous schedule. See [Asynchronous Schedule](#) for complete operational details.

57.4.3.4.1 Example - Preserving Micro-Frame Integrity

One of the requirements of a USB host controller is to maintain Frame Integrity. This means that the HC must preserve the micro-frame boundaries.

For example, SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of micro-frame timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One implication of this responsibility is that the HC must ensure that it does not start transactions that do not complete before the end of the micro-frame. More precisely, no transactions should be started by the host controller, which do not complete in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it completes before the end of the micro-frame.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction takes. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch all of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers can allow the host controller to know exactly whether there is enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the micro-frame. It is a reasonable assumption that software never over-commits the micro-frame to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some circumstances a transaction is not executed that could have been executed. However, under all circumstances, a transaction is never started unless there is enough time in the frame to complete the transaction.

57.4.3.4.1.1 Transaction Fit - A Best-Fit Approximation Algorithm

A curve is calculated which represents the latest start time for every packet size, at which software schedules the start of a periodic transaction.

This curve is the 80% bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each packet size can be started and completed, in the micro-frame. A plot of these two curves are illustrated in Figure 57-8. The plot Y-axis represents the number of byte-times left in a frame.

The space between the 80% and the Last Start plots is bandwidth reclamation area. In this algorithm the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function ($f(x)$) between the 80% and Last Start curves. The function $f(x)$ adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land above the function curve. The host controller will not start transactions whose results land below the function curve.

The following figure illustrates the Best-Fit Approximation.

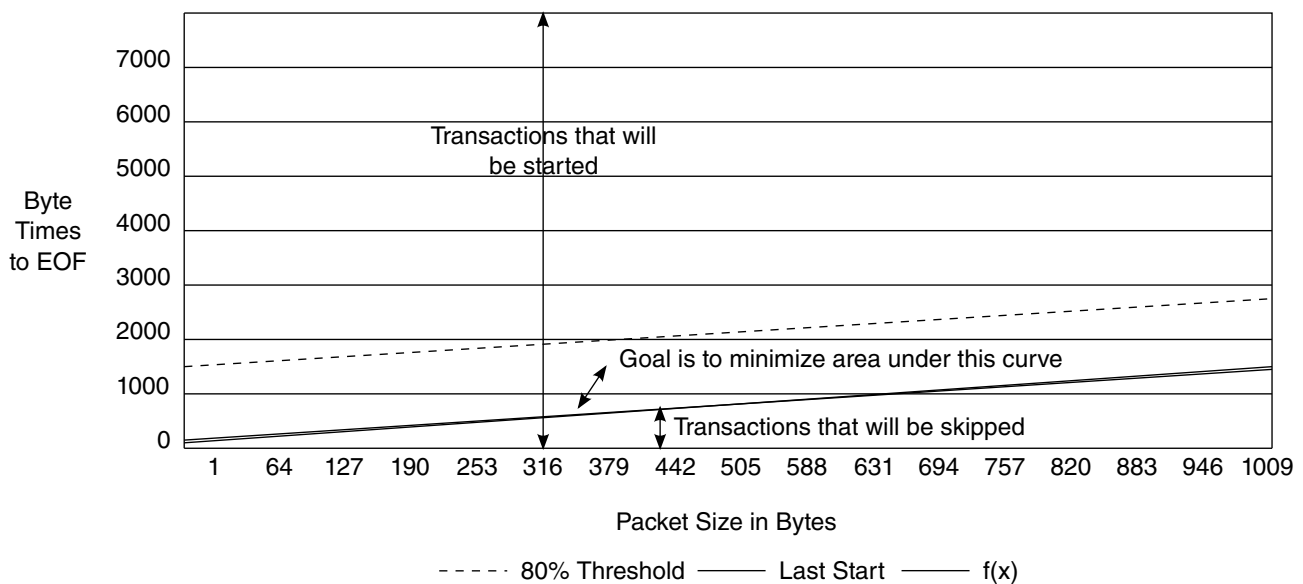

Figure 57-8. Best Fit Approximation

The LastStart line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used is a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in the table below. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

Table 57-37. Example Worse-case Transaction Timing Components

Component	Bit time	Byte Time	Explanation
-----------	----------	-----------	-------------

Table continues on the next page...

Table 57-37. Example Worse-case Transaction Timing Components (continued)

Split Token	76	9.5	Split token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Number of bit times required between consecutive host packets.
Token	67	8.375	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Data Packet (0 data bytes)	66.7	8.34	Zero-length data packet. Includes sync, PID, crc16, eop, and so on.
Turnaround time	721	90.125	Time for packet initiator (Host) to see the beginning of a response to a transmitted packet.
Handshake packet	48	6	Handshake packet as defined in USB core specification. Includes sync, PID, eop, and so on.
		144	Total

The exact details of the function ($f(x)$) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the Last Start curve, without dipping below the LastStart line, while at the same time keeping the check as simple as possible for hardware implementation. The $f(x)$ in [Figure 57-8](#) was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```

Algorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)
Begin
Local Temp = MaximumPacketSize + 192
Local rvalue = TRUE
If MaximumPacketSize >= 128 then
    Temp += 128
End If
If Temp > HC_BytesLeftInFrame then
    Rvalue = FALSE
End If
Return rvalue
End

```

This algorithm takes two inputs, the current maximum packet size of the transaction and the hardware counter of the number of bytes left in the current micro-frame. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is greater than or equal to 128 bytes, then an additional constant of 128 is added to the running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the $f(x)$ plot was getting close to the LastStart line.

57.4.3.5 Periodic Schedule Frame Boundaries vs Bus Frame Boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned.

Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions through a micro-frame pipeline (see start- (SS) and complete- (CS) splits illustrated in the following figure). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

Figure 57-9. Frame Boundary Relationship between HS bus and FS/LS Bus

The simple projection, as the above figure illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement one micro-frame phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed through the Frame List Index Register (USB_FRINDEX) documented in [USB Frame Index \(USB_nFRINDEX\)](#) and initially illustrated in [Schedule Traversal Rules](#). Bits FRINDEX[2:0], represent the micro-frame number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and the SOF value are increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one micro-frame. The one micro-frame delay yields host controller periodic schedule and bus frame boundary relationship as illustrated in the following figure. This adjustment allows software to trivially schedule the periodic start and

complete-split transactions for full-and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

The following figure illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined: The host controller's view of the 1 msec boundaries is called H-Frames. The high-speed bus's view of the 1 msec boundaries is called B-Frames.

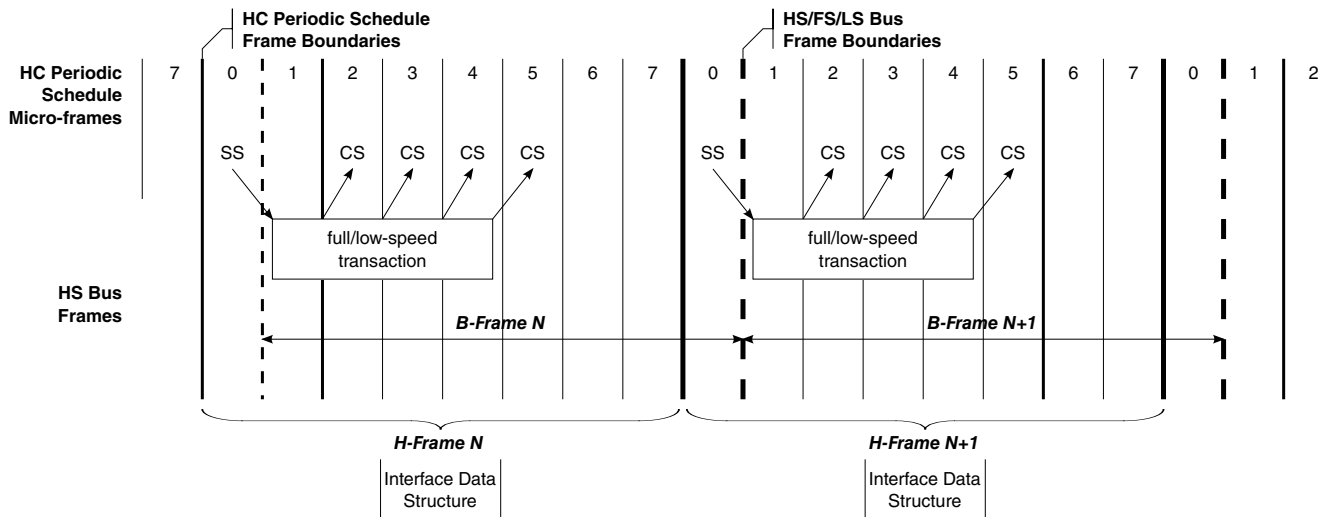

Figure 57-10. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries

H-Frame boundaries for the host controller correspond to increments of $FRINDEX[13:3]$. Micro-frame numbers for the H-Frame are tracked by $FRINDEX[2:0]$. B-Frame boundaries are visible on the high-speed bus through changes in the SOF token's frame number. Micro-frame numbers on the high-speed bus are only derived from the SOF token's frame number (that is the high-speed bus sees eight SOFs with the same frame number value). H-Frames and B-Frames have the fixed relationship (that is B-Frames lag H-Frames by one micro-frame time) illustrated in the figure above. The host controller's periodic schedule is naturally aligned to H-Frames. Software schedules transactions for full- and low-speed periodic endpoints relative the H-Frames. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in [USB Frame Index \(\$USB_nFRINDEX\$ \)](#), the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the $FRINDEX$ register bits $[13:3]$ by one micro-frame count. This lag behavior can be accomplished by incrementing $FRINDEX[13:3]$ based on carry-out on the 7 to 0 increment of $FRINDEX[2:0]$ and incrementing SOFV based on the transition of 0 to 1 of $FRINDEX[2:0]$.

Software is allowed to write to FRINDEX. [USB Frame Index \(USB_nFRINDEX\)](#) provides the requirements that software should adhere when writing a new value in FRINDEX.

The table below illustrates the required relationship between the value of FRINDEX and the value of SOFV.

Table 57-38. Operation of FRINDEX and SOFV (SOF Value Register)

Current			Next		
FRINDEX[F]	SOFV	FRINDEX[mF]	FRINDEX[F]	SOFV	FRINDEX[mF]
N	N	111b	N+1	N	000b
N+1	N	000b	N+1	N+1	001b
N+1	N+1	001b	N+1	N+1	010b
N+1	N+1	010b	N+1	N+1	011b
N+1	N+1	011b	N+1	N+1	100b
N+1	N+1	100b	N+1	N+1	101b
N+1	N+1	101b	N+1	N+1	110b
N+1	N+1	110b	N+1	N+1	111b

NOTE

Where [F] = [13:3]; [mF] = [2:0]

57.4.3.6 Periodic Schedule

The periodic schedule traversal is enabled or disabled through the Periodic Schedule Enable bit in the USB_USBCMD register. If the Periodic Schedule Enable bit is set to zero, then the host controller simply does not try to access the periodic frame list through the USB_PERIODICLISTBASE register. Likewise, when the Periodic Schedule Enable bit is one, then the host controller does use the USB_PERIODICLISTBASE register to traverse the periodic schedule.

The host controller will not react to modifications to the Periodic Schedule Enable immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the Periodic Schedule Enable bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b micro-frame. These work items must be removed from the schedule before the Periodic Schedule Enable bit is written to zero.

The Periodic Schedule Status bit in the USB_USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing one (or zero) to the Periodic Schedule Enable bit in the USB_USBCMD register. Software then can poll the Periodic Schedule Status bit to determine when the periodic

schedule has made the desired transition. Software must not modify the Periodic Schedule Enable bit unless the value of the Periodic Schedule Enable bit equals that of the Periodic Schedule Status bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions.

The following figure illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

Figure 57-11. Example Periodic Schedule

57.4.3.7 Managing Isochronous Transfers Using iTDs

The structure of an iTD is presented in [Isochronous \(High-Speed\) Transfer Descriptor \(iTD\)](#). The four distinct sections to an iTD:

- The first field is the Next Link Pointer. This field is for schedule linkage purposes only.
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one micro-frame's worth of transactions for a single high-speed isochronous endpoint.
- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4 K aligned pointers to physical memory.
- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

57.4.3.7.1 Host Controller Operational Model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Therefore, each transaction descriptor corresponds to one micro-frame. Each iTD can span 8 micro-frames worth of transactions.

When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array.

If the active bit in the Status field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the Next pointer to the next schedule data structure.

When the indexed active bit is one, the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, and so on.). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if PG field is 0, then the host controller stores Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses the endpoint addressing information and I/O-bit to execute a transaction to the appropriate endpoint. When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (for example, page 0 pointer) selected by the active transaction descriptions' PG (for example, value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer crosses a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (for example, page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes through the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of Maximum Packet sized bus transactions for the endpoint in the current micro-frame. In other words, the Mult field represents a transaction count for the endpoint in the current micro-frame. If the Mult field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers, the value of the Transaction X Length field represents the total bytes to be sent during the micro-frame. The Mult field must be set by software to be consistent with Transaction X Length and Maximum Packet Size. The host controller sends the bytes in Maximum Packet Size'd portions. After each transaction, the host controller decrements its local copy of Transaction X Length by Maximum Packet Size. The number of bytes the host controller sends is always Maximum Packet Size or Transaction X Length, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues Mult transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use Maximum Packet Size to detect packet babble errors. The host controller keeps the sum of bytes received in the Transaction X Length field. After all transactions for the endpoint have completed for the micro-frame, Transaction X Length contains the total bytes received. If the final value of Transaction X Length is less than the value of Maximum Packet Size, then less data than was allowed for was received from the associated endpoint. This short packet condition does not set

the USBINT bit in the USB_USBSTS register to one. The host controller will not detect this condition. If the device sends more than Transaction X Length or Maximum Packet Size bytes (whichever is less), then the host controller sets the Babble Detected bit to one and set the Active bit to zero. Note, that the host controller is not required to update the iTD field Transaction X Length in this error scenario. If the Mult field is greater than one, then the host controller automatically executes the value of Mult transactions. The host controller will not execute all Mult transactions if:

- The endpoint is an OUT and Transaction X Length goes to zero before all the Mult transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed. The end of micro-frame may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next micro-frame. Refer to Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

57.4.3.7.2 Software Operational Model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N micro-frames. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

The following figure illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (that is the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one micro-frame's worth of transactions. The EHCI controller does not provide per-transaction results within a micro-frame. It treats the per-micro-frame transactions as a single logical transfer. On the left is the host controller's frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

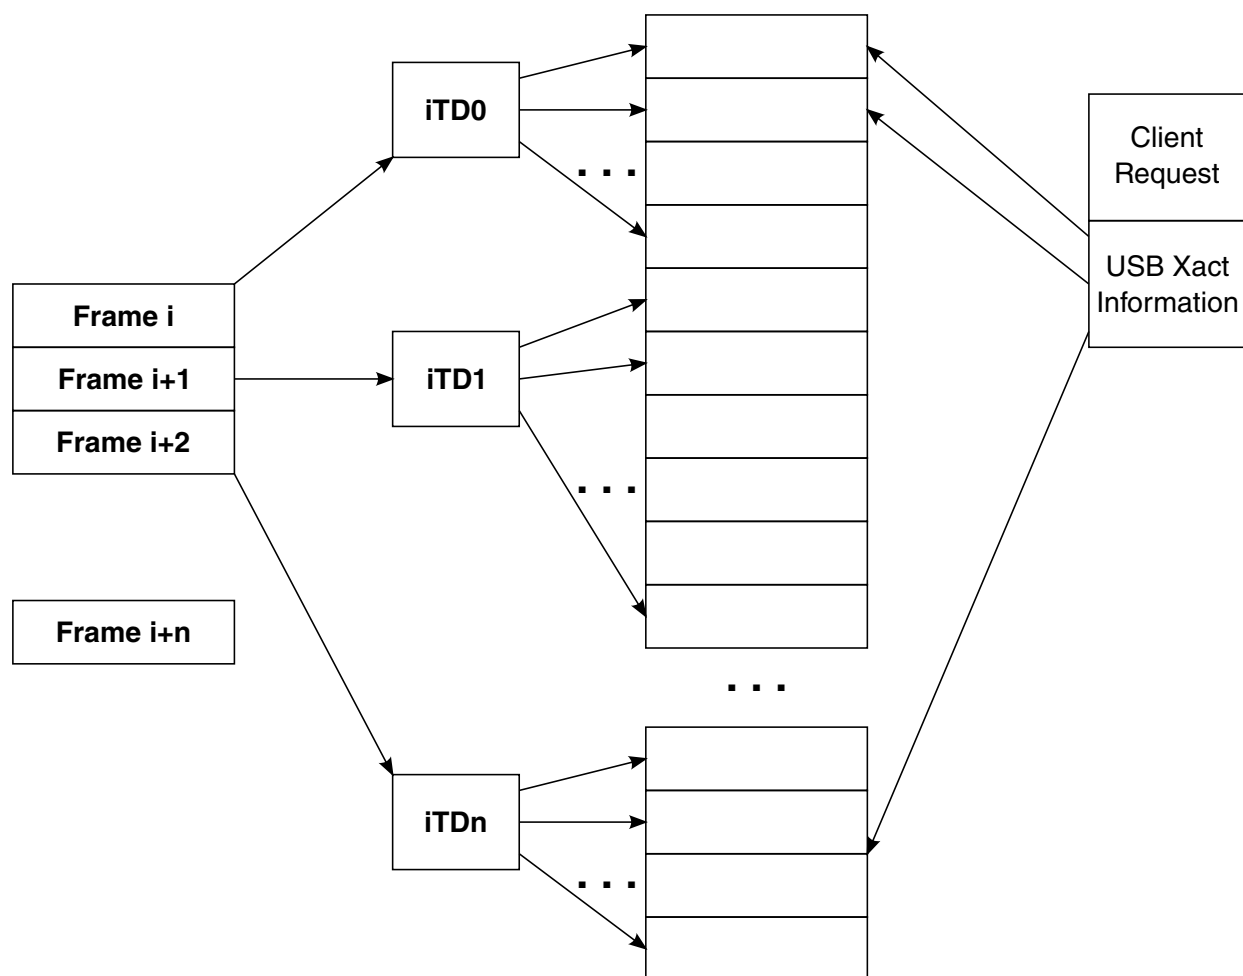

Figure 57-12. Example Association of iTDs to Client Request Buffer

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page (for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the transaction offset field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer wraps a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to 'alias' the page selector to Page zero. USB 2.0 isochronous

endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to one.

57.4.3.7.2.1 Periodic scheduling threshold

The Isochronous Scheduling Threshold field in the USB_HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures.

It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 micro-frames worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. Three basic caching models that account for the fact the isochronous data structures span 8 micro-frames. The three caching models are: no caching, micro-frame caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the USB_FRINDEX register to determine the current frame and micro-frame the host controller is currently executing. Of course, there is no information about where in the micro-frame the host controller is, so a constant uncertainty-factor of one micro-frame has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the Isochronous Scheduling Threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per micro-frame) but always dumps any accumulated schedule state at the end of the micro-frame. At the appropriate time relative to the beginning of every micro-frame, the host controller always begins schedule traversal from the frame list. Software can use the value of the USB_FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 micro-frames in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the Isochronous Scheduling Threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 micro-frames). Software uses the value of the USB_FRINDEX register (plus the constant 1

uncertainty) to determine the current micro-frame/frame (assume modulo 8 arithmetic in adding the constant 1 to the micro-frame number). For any current frame N, if the current micro-frame is 0 to 6, then software can safely add isochronous transactions to Frame N + 1. If the current micro-frame is 7, then software can add isochronous transactions to Frame N + 2.

Micro-frame caching is indicated with a non-zero value in the least-significant 3 bits of the Isochronous Scheduling Threshold field. System software assumes the host controller caches one or more periodic data structures for the number of micro-frames indicated in the Isochronous Scheduling Threshold field. For example, if the count value were 2, then the host controller keeps a window of 2 micro-frames worth of state (current micro-frame, plus the next) on-chip. On each micro-frame boundary, the host controller releases the current micro-frame state and begins accumulating the next micro-frame state.

57.4.3.8 Asynchronous Schedule

The Asynchronous schedule traversal is enabled or disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

If the Asynchronous Schedule Enable bit is set to zero, then the host controller simply does not try to access the asynchronous schedule through the USB_ASYNCLISTADDR register. Likewise, when the Asynchronous Schedule Enable bit is one, then the host controller does use the USB_ASYNCLISTADDR register to traverse the asynchronous schedule. Modifications to the Asynchronous Schedule Enable bit are not necessarily immediate. Rather the new value of the bit is taken into consideration the next time the host controller needs to use the value of the USB_ASYNCLISTADDR register to get the next queue head.

The Asynchronous Schedule Status bit in the USB_USBSTS register indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing one (or zero) to the Asynchronous Schedule Enable bit in the USB_USBCMD register. Software then can poll the Asynchronous Schedule Status bit to determine when the asynchronous schedule has made the desired transition. Software must not modify the Asynchronous Schedule Enable bit unless the value of the Asynchronous Schedule Enable bit equals that of the Asynchronous Schedule Status bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the USB_ASYNCLISTADDR register. The default value of the USB_ASYNCLISTADDR register after reset is undefined and the schedule is disabled when the Asynchronous Schedule Enable bit is zero.

Software may only write this register with defined results when the schedule is disabled. For example, Asynchronous Schedule Enable bit in the USB_USBCMD and the Asynchronous Schedule Status bit in the USB_USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting the Asynchronous Schedule Enable bit to one. The asynchronous schedule is actually enabled when the Asynchronous Schedule Status bit is one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the USB_ASYNCLISTADDR register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller completes processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the USB_ASYNCLISTADDR register. Next time the asynchronous schedule is accessed, this is the first data structure that is serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller completes processing the asynchronous schedule when one of the following events occur:

- The end of a micro-frame occurs.
- The host controller detects an empty list condition (see [Empty Asynchronous Schedule Detection](#))
- The schedule has been disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in [Figure 57-7](#). Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iTDD or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

57.4.3.8.1 Adding Queue Heads to Asynchronous Schedule

This is a software requirement section.

There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the USB_ASYNC_LIST_ADDR register, then enables the list by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example, qTD pointers have T-Bits set to one or reference valid qTDs and the Horizontal Pointer references a valid queue head data structure. The following algorithm represents the functional requirements:

```

InsertQueueHead (pQHeadCurrent, pQueueHeadNew)
--
-- Requirement: all inputs must be properly initialized.
--
-- pQHeadCurrent is a pointer to a queue head that is
-- already in the active list
-- pQHeadNew is a pointer to the queue head to be added
--
-- This algorithm links a new queue head into a existing
-- list
--
pQueueHeadNew.HorizontalPointer = pQueueHeadCurrent.HorizontalPointer
pQueueHeadCurrent.HorizontalPointer = physicalAddressOf (pQueueHeadNew)
End InsertQueueHead

```

57.4.3.8.2 Removing Queue Heads from Asynchronous Schedule

This is a software requirement section.

There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list.

Software deactivates the asynchronous schedule by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to zero. Software can determine when the list is idle when the Asynchronous Schedule Status bit in the USB_USBSTS register is zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list through the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```

UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)
--
-- Requirement: all inputs must be properly initialized.
--
-- pQHeadPrevious is a pointer to a queue head that
-- references the queue head to remove
-- pQHeadToUnlink is a pointer to the queue head to be

```

USB Operation Model

```
-- removed
-- pQheadNext is a pointer to a queue head still in the
-- schedule. Software provides this pointer with the
-- following strict rules:
--     if the host software is one queue head, then
--     pQheadNext must be the same as
--     QueueheadToUnlink.HorizontalPointer. If the host
--     software is unlinking a consecutive series of
--     queue heads, QheadNext must be set by software to
--     the queue head remaining in the schedule.
--
-- This algorithm unlinks a queue head from a circular list
--
pQueueHeadPrevious.HorizontalPointer = pQueueHeadToUnlink.HorizontalPointer
pQueueHeadToUnlink.HorizontalPointer = pQheadNext
```

End UnlinkQueueHead

If software removes the queue head with the H-bit set to one, it must select another queue head still linked into the schedule and set its H-bit to one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its H-bit set to one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, and so on). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (Interrupt on Async Advance Doorbell bit in the USB_USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (Interrupt on Async Advance bit in the USB_USBSTS register) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to one, it also sets the command bit to zero. The third bit is an interrupt enable (Interrupt on Async Advance bit in the USB_USBINTR register) that is matched with the status bit. If the status bit is one and the interrupt enable bit is one, then the host controller asserts a hardware interrupt.

The figure below illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that remains in the asynchronous schedule.

When the host controller observes that doorbell bit being set to one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A and B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (that is traversed beyond queue head (B) in this example). The following figure illustrates the generic queue head unlink scenario.

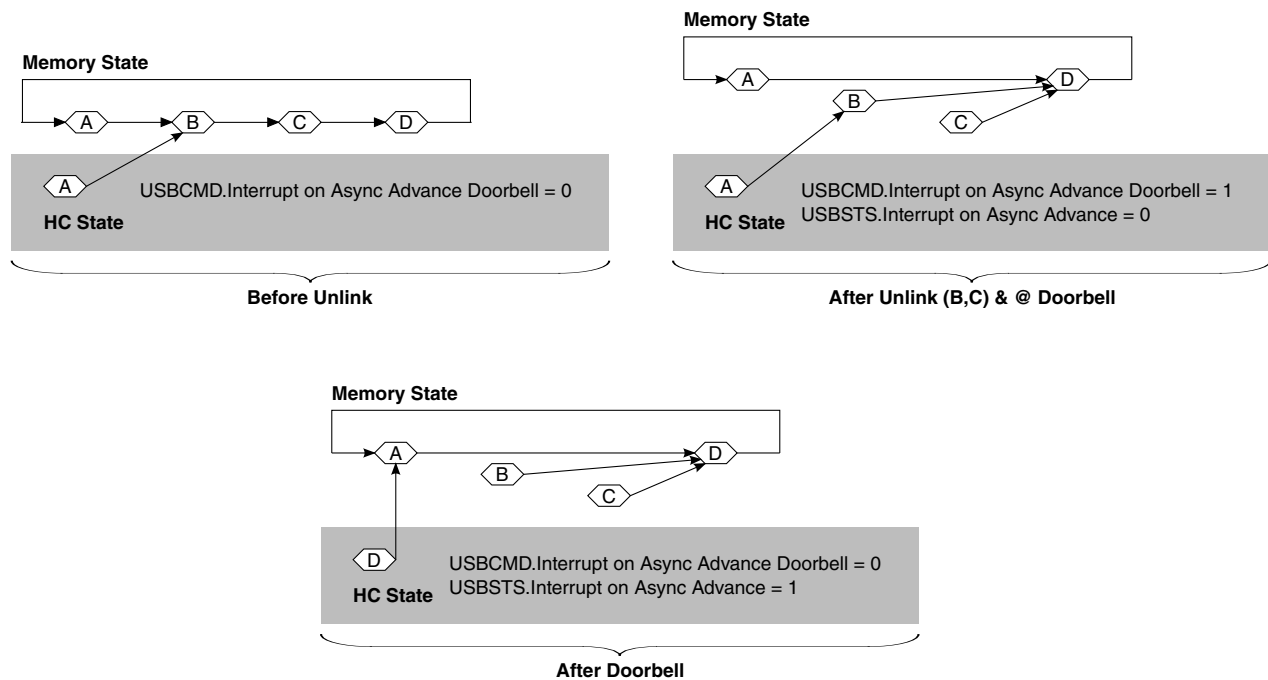

Figure 57-13. Generic Queue Head Unlink Scenario

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting the Advance on Async status bit to one.

Software may re-use the memory associated with the removed queue heads after it observes the Interrupt on Async Advance status bit is set to one, following assertion of the doorbell. Software should acknowledge the Interrupt on Async Advance status as indicated in the USB_USBSTS register, before using the doorbell handshake again.

57.4.3.8.3 Empty Asynchronous Schedule Detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty.

The queue head data structure (see [Table 57-24](#)) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USB_USBSTS register (*Reclamation*) that is set to zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see [Asynchronous schedule traversal: Start Event](#)).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is shown in the following figure.

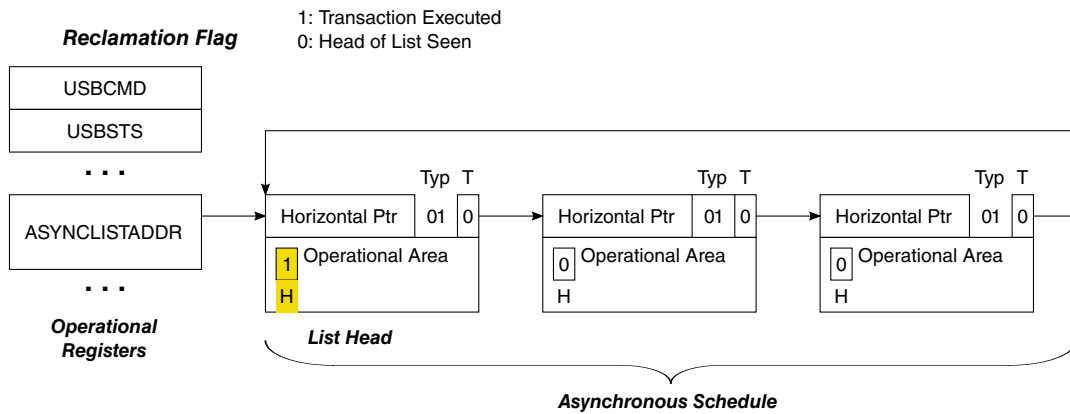

Figure 57-14. Asynchronous Schedule List w/Annotation to Mark Head of List

Software must ensure there is at most one queue head with the *H-bit* set to one, and that it is always coherent with respect to the schedule.

57.4.3.8.4 Restarting Asynchronous Schedule Before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the micro-frame.

It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the micro-frame. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the host controller ceases traversal of the Asynchronous schedule very early in the micro-frame. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current micro-frame, instead of waiting

until the next micro-frame. When the reason for host controller idling asynchronous schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

57.4.3.8.4.1 Example Method for Restarting Asynchronous Schedule Traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: *how long should the host controller stay idle before restarting?*

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called *AsyncSchedSleepTime*, and has a value of 10 μ sec. The value is derived based on the analysis in [Example Derivation for AsyncSchedSleepTime](#). The traversal algorithm is simple:

- Traverse the Asynchronous schedule until the either an End-Of-micro-Frame event occurs, or an empty list is detected. If the event is an End-of-micro-Frame, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a *schedule sleep* state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to *schedule active* state. The start context allows the HC to reload *Nakcnt* fields, and so on. So the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each micro-frame. The figure below illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.

Figure 57-15. Example State Machine for Managing Asynchronous Schedule Traversal

The actions referred to in the figure above are defined in the following table.

Table 57-39. Asynchronous Schedule SM Transition Actions

Action	Action Description Label
A	On detection of the empty list, the host controller sets the <i>AsynchronousTraversalSleepTimer</i> to <i>AsynSchedSleepTime</i> .
B	When the <i>AsynchronousTraversalSleepTimer</i> expires, the host controller sets the <i>Reclamation</i> bit in the USBSTS register to one and moves the Nak Counter reload state machine to <i>WaitForListHead</i> (see Nak Count Reload Control).
C	The host controller cancels the sleep timer (<i>AsynchronousTraversalSleepTimer</i>).

57.4.3.8.4.2 Async Sched Not Active

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine does not leave this state when the *Asynchronous Schedule Enable* bit in the USB_USBCMD register is zero.

This state is entered from Async Sched Active or Async Sched Sleeping states when the end-of-micro-frame event is detected.

57.4.3.8.4.3 Async Sched Active

This state is entered from the Async Sched Not Active state when the periodic schedule is not active. It is also entered from the Async Sched Sleeping states when the *AsynchrhonousTraversalSleepTimer* expires. On every transition into this state, the host controller sets the *Reclamation* bit in the USB_USBSTS register to one.

While in this state, the host controller continually traverses the asynchronous schedule until either the end of micro-frame or an empty list condition is detected.

57.4.3.8.4.4 Async Sched Sleeping

The state is entered from the Async Sched Active state when a schedule empty condition is detected. On entry to this state, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.

57.4.3.8.4.5 Example Derivation for AsyncSchedSleepTime

The derivation is based on analysis of what work the host controller could be doing next.

It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests.

The table below summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (for example *footprint*, or *wall clock*) the transaction takes to complete.

Table 57-40. Typical Low-/Full-speed Transaction Times

Transaction Attributes		Footprint (time)	Description
Speed	HS	11.9 ms	Maximum foot print for a worst-case, full-sized bulk data transaction.
Size	512	9.45 ms	Maximum footprint for an approximate best-case, full-sized bulk data transaction.
Type	Bulk		
Speed	FS	~50 ms	Approximate typical for full-sized bulk data. An 8-byte low-speed is about 2x, or between 90 and 100 ms.
Size	64		
Type	Bulk		
Speed	FS	~12 ms	Approximate typical for 8-byte bulk/control (that is setup)
Size	8		
Type	Cntrl		

A *AsyncSchedSleepTime* value of 10 μ s provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller gets the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10 μ s sleep period would allow the host controller to get the NAK results on the first complete-split.

57.4.3.8.5 Asynchronous schedule traversal: *Start Event*

Once the HC has *idled* itself through the empty schedule detection (Section 0), it will naturally *activate* and begin processing from the Periodic Schedule at the beginning of each micro-frame.

In addition, it may have idled itself early in a micro-frame. When this occurs (idles early in the micro-frame) the HC must occasionally *re-activate* during the micro-frame and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in [Restarting Asynchronous Schedule Before EOF](#). Asynchronous schedule *Start Events* are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the micro-frame is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state (see [Restarting Asynchronous Schedule Before EOF](#)).

57.4.3.8.6 Reclamation Status Bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (see [Empty Asynchronous Schedule Detection](#)) depends on the proper management of the *Reclamation* bit in the USB_USBSTS register. The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (see [Fetch Queue Head](#)).

The host controller is required to set the *Reclamation* bit to one whenever an asynchronous schedule traversal *Start Event*, as documented in [Asynchronous schedule traversal: Start Event](#), occurs. The *Reclamation* bit is also set to one whenever the host controller executes a transaction while traversing the asynchronous schedule (see [Execute Transaction](#)). The host controller sets the *Reclamation* bit to zero whenever it finds a queue head with its *H-bit* set to one. Software should only set a queue head's *H-bit* if the queue head is in the asynchronous schedule. If software sets the *H-bit* in an interrupt queue head to one, the resulting behavior is undefined. The host controller may set the *Reclamation* bit to zero when executing from the periodic schedule.

57.4.3.9 Operational Model for Nak Counter

This section describes the operational model for the *NakCnt* field defined in a queue head.

See [Queue Head Initialization](#) for more information. Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control through the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced through the same asynchronous schedule. The time between the *Start-split* transaction and the first *Complete-split* transaction could be very short (that is like when the endpoint is the only one in the asynchronous schedule). The hub NYETs (effectively Naks) the *Complete-split* transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which does not complete until after the transaction on the classic bus completes.

The two component fields in a queue head to support the throttling feature: a counter field (*NakCnt*), and a counter reload field (*RL*). *NakCnt* is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. The two operational modes associated with this counter:

- Not Used- This mode is set when the *RL* field is zero. The host controller ignores the *NakCnt* field for any execution of transactions through a queue head with an *RL* field of zero. Software must use this selection for interrupt endpoints.
- Nak Throttle Mode- This mode is selected when the *RL* field is non-zero. In this mode, the value in the *NakCnt* field represents the maximum number of Nak or Nyet responses the host controller tolerates on each endpoint. In this mode, the HC decrements the *NakCnt* field based on the token/handshake criteria listed in the table below. The host controller must reload *NakCnt* when the endpoint successfully moves data (for example, policy to reward device for moving data).

The following table describes the *NakCnt* field adjustment rules.

Table 57-41. NakCnt Field Adjustment Rules

Token	Handshake	
	Handshake NAK	NYET
IN/PING	decrement <i>NakCnt</i>	N/A (protocol error)
OUT	decrement <i>NakCnt</i>	No Action ¹ Start
Split	decrement <i>NakCnt</i>	N/A (protocol error)
Complete Split	No Action	Decrement <i>NakCnt</i>

1. Recommended behavior on this response is to reload *NakCnt*

In summary, system software enables the counter by setting the reload field (*RL*) to a non-zero value. The host controller may execute a transaction if *NakCnt* is non-zero. The host controller does not execute a transaction if *NakCnt* is zero. The reload mechanism is described in detail in [Nak Count Reload Control](#) .

NOTE

When all queue heads in the Asynchronous Schedule either exhausts all transfers or all *NakCnt*'s go to zero, then the host controller detects an empty Asynchronous Schedule and idle schedule traversal (see [Empty Asynchronous Schedule Detection](#)).

Any time the host controller begins a new traversal of the Asynchronous Schedule, a *Start Event* is assumed, see [Asynchronous schedule traversal: Start Event](#). Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

57.4.3.9.1 Nak Count Reload Control

When the host controller reaches the *Execute Transaction* state for a queue head (meaning that it has an active operational state), it checks to determine whether the *NakCnt* field should be reloaded from *RL* (see [Execute Transaction](#)). If the answer is yes, then *RL* is copied into *NakCnt*. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (*NakCnt* see [Table 57-24](#)) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see [Asynchronous schedule traversal: Start Event](#) for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see [Figure 57-14](#)).

The following figure illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: *Execute Transaction* (see the figure below). The host controller does not perform the nak counter reload operation if the *RL* field (see [Table 57-24](#)) is set to zero.

Figure 57-16. Example HC State Machine for Controlling Nak Counter Reloads

57.4.3.9.1.1 Wait for List Head

This is the initial state.

The state machine enters this state from Wait for Start Event when a start event as defined in [Asynchronous schedule traversal: Start Event](#) occurs.

The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule.

This occurs when the host controller fetches a queue head whose *H-bit* is set to one.

57.4.3.9.1.2 Do Reload

This state is entered from the Wait for List Head state when the host controller fetches a queue head with the *H-bit* set to one. While in this state, the host controller performs nak counter reloads for every queue head visited that has a non-zero nak reload value (*RL*) field.

57.4.3.9.1.3 Wait for Start Event

This state is entered from the *Do Reload* state when a queue head with the *H-bit* set to one is fetched. While in this state, the host controller does not perform nak counter reloads.

57.4.3.10 Managing Control/Bulk/Interrupt Transfers through Queue Heads

This section presents an overview of how the host controller interacts with queuing data structures.

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in [Table 57-24](#)). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a *transfer*.

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,
- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area,
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller sets one (or more) of the error reporting bits in the queue head's *Status* field. The *Status* field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the queue head *Status* field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions occurs for the endpoint and the host controller does not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in the following figure. This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the *Fetch QH* state in order to avoid all hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and *activate* them, then the host controller always *find* them if/when they are reachable. The figure below illustrates the Host Controller Queue Head Traversal State Machine.

Figure 57-17. Host Controller Queue Head Traversal State Machine

This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The Execute Transaction state (see [Execute](#)

[Transaction](#)) describes the basic requirements for all endpoints. [Split Transactions for Asynchronous Transfers](#) and [Split Transaction Interrupt](#) describe details of the required extensions to the Execute Transaction state for endpoints requiring split transactions.

NOTE

Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see Section Queue Head for layout of a queue head):

Valid static endpoint state.

- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the *Next qTD Pointer* field value to reference a valid qTD.

57.4.3.10.1 Fetch Queue Head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register (see [Next Asynch. Address \(USB_nASYNCLISTADDR\)](#))/ [Endpoint List Address \(USB_nENDPTLISTADDR\)](#) Additionally, it may be referenced from the *Next LinkPointer* field of an iTD, siTD, FSTN or another Queue Head. If the referencing link pointer has the *Typ* field set to indicate a queue head, it is assumed to reference a queue head structure as defined in [Table 57-24](#).

While in this state, the host controller performs operations to implement empty schedule detection (see [Empty Asynchronous Schedule Detection](#)) and Nak Counter reloads (see [Operational Model for Nak Counter](#)). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (that is *S-mask* is zero), and
- The *H-bit* is one, and
- The *Reclamation* bit in the USBSTS register is zero.

When these criteria are met, the host controller stops traversing the asynchronous list (as described in [Empty Asynchronous Schedule Detection](#)). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the *H-bit* is one and the *Reclamation* bit is one, then the host controller sets the *Reclamation* bit in the USBSTS register to zero before completing this state. The operations for reloading of the Nak Counter are described in detail in [Operational Model for Nak Counter](#).

This state is complete when the queue head has been read on-chip.

57.4.3.10.2 Advance Queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the FetchQHD state if the overlay *Active* and *Halt* bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and determines whether or not to perform an overlay.

NOTE

If the *I-bit* is one and the *Active* bit is zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field *Bytes to Transfer* is not zero and the *T-bit* in the *Alternate Next qTD Pointer* is set to zero, then the host controller uses the *Alternate Next qTD Pointer*. Otherwise, the host controller uses the *NextqTD Pointer*. If *NextqTD Pointer's T-bit* is set to one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has its *Active* bit set to one, the host controller moves the pointer value used to reach the qTD (*Next* or *Alternate Next*) to the *Current qTD Pointer* field, then performs the overlay. If the fetched qTD has its *Active* bit set to zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure.

The host controller performs the overlay based on the following rules:

- The value of the data toggle (*dt*) field in the overlay area depends on the value of the *data toggle control (dtc)* bit (see [Table 57-26](#)).
- If the *EPS* field indicates the endpoint is a high-speed endpoint, the *Ping* state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- *C-prog-mask* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *Frame Tag* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *NakCnt* field in the overlay area is loaded from the *RL* field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.

57.4.3.10.3 Execute Transaction

The host controller enters this state from the Fetch Queue Head state only if the *Active* bit in *Status* field of the queue head is set to one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's *S-mask* field contains a non-zero value. It is the responsibility of software to ensure the *S-mask* field is appropriately initialized based on the transfer type. There are other criteria that must be met if the *EPS* field indicates that the endpoint is a low- or full-speed endpoint, see [Split Transactions for Asynchronous Transfers](#) and [Split Transaction Interrupt](#) .

57.4.3.10.3.1 Interrupt Transfer Pre-condition Criteria

If the queue head is for an interrupt endpoint (for example, non-zero *S-mask* field), then the FRINDEX[2:0] field must identify a bit in the *S-mask* field that has one in it.

For example, an *S-mask* value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction.

57.4.3.10.3.2 Asynchronous Transfer Pre-operations and Pre-condition Criteria

If the queue head is not for an interrupt endpoint (for example, zero *S-mask* field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria.

The pre-operation is:

Checks the Nak counter reload state ([Operational Model for Nak Counter](#)). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the *NakCnt* field has been reloaded, the host controller checks the value of the *NakCnt* field in the queue head. If *NakCnt* is non-zero, or if the *Reload Nak Counter* field is zero, then the host controller considers this queue head for a transaction.

57.4.3.10.3.3 Transfer Type Independent Pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter *qHTransactionCounter* is loaded from the queue head's *Mult* field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the *Mult* field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the micro-frame to complete this transaction (see [Transaction Fit - A Best-Fit Approximation Algorithm](#) for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of *qHTransactionCounter* for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the *Reclamation* bit in the USBSTS register to one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates *qHTransactionCounter* times in this state executing transactions. After each transaction is executed, *qHTransactionCounter* is decremented by one. The host controller exits this state when one of the following events occurs:

- The *qHTransactionCounter* decrements to zero, or
- The endpoint responds to the transaction with any handshake other than an ACK,⁴ or
- The transaction experiences a transaction error, or
- The *Active* bit in the queue head goes to zero, or
- There is not enough time in the micro-frame left to execute the next transaction(see [Transaction Fit - A Best-Fit Approximation Algorithm](#)) for example method for implementing the frame boundary test).

NOTE

For a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the *Total Bytes to Transfer* field is decremented by the number of bytes moved in the transaction, the data toggle bit (*dt*) is toggled, the current page offset is advanced to the next appropriate value (for example,

advanced by the number of bytes successfully moved), and the *C_Page* field is updated to the appropriate value (if necessary). See [Buffer Pointer List Use for Data Streaming with qTDs](#) .

NOTE

The *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller executes zero-length transaction to the endpoint. If the *PID_Code* field indicates an IN transaction and the device delivers data, the host controller detects a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement *qHTransactionCounter*). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of *qHTransactionCounter* is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and *RL* is non-zero, *NakCnt* is decremented by one. If *RL* is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of *CErr* did not change). Software should set the *RL* field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly *NakCnt*, the host controller writes back the results of the transaction to the queue head's overlay area in main memory).

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *MaximumPacket Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The *CErr* field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in [Transaction Error](#) .

The following events causes the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from one to zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to zero. When this occurs the *Halted* bit is set to one and *Active* is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to one and the *Active* bit is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The *Total Bytes to Transfer* field is zero after the transaction completes.
 - For a zero length transaction, it was zero before the transaction was started. When this condition occurs, the *Active* bit is set to zero.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to zero and a short packet condition exists. The short-packet condition is detected during the Advance Queue state. Refer to [Split Transactions](#) for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (for example *Maximum Packet Length* or *Total Bytes to Transfer* bytes, whichever is less) (for example a packet babble). This results in the host controller setting the *Halted* bit to one.

- NakCnt, dt, Total Bytes to Transfer, C_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

57.4.3.10.3.4 Halting a Queue Head

A halted endpoint is defined only for the transfer types that are managed through queue heads (control, bulk and interrupt).

The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USB_n_USBSTS register to one. To halt the queue head, the *Active* bit is set to zero and the *Halted* bit is set to one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller does not advance the transfer state on a transaction that results in a *Halt* condition (for example no updates necessary for *Total Bytes to Transfer*, *C_Page*, *Current Offset*, and *dt*). The host controller must update *CErr* as appropriate. When a queue head is halted, the *USB Error Interrupt* bit in the USB_n_USBSTS register is set to one. If the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is set to one, a hardware interrupt is generated at the next interrupt threshold.

57.4.3.10.3.5 Asynchronous Schedule Park Mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule.

This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the *Mult* feature that is used in the Periodic schedule. Where-as the *Mult* feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in [Execute Transaction](#) apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the *Asynchronous Schedule Park Capability* bit in the USB_n_HCCPARAMs register to one. This information keys system software that the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USB_n_USBCMD register are modifiable. System software enables the feature by writing a one to the *Asynchronous Schedule Park Mode Enable* bit.

When park-mode is not enabled (for example *Asynchronous Schedule Park Mode Enable* bit in the USB_n_USBCMD register is zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose *EPS* field indicates a Low/Full-speed device (for example only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose *EPS* field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose *EPS* field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the *Asynchronous Schedule Park Mode Count* field in the USB_n_USBCMD register. Software must not set *Asynchronous Schedule Park Mode Enable* bit to one and also set *Asynchronous Schedule Park Mode Count* field to zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in [Execute Transaction](#). It only effects how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the *Mult* field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter *PM-Count* from *Asynchronous Schedule Park Mode Count* when *Asynchronous Schedule Park Mode Enable* bit is one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, *PM-Count* is decremented. The host controller may continue to execute bus transactions from the current queue head until *PM-Count* goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake.

The following table summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

Table 57-42. Actions for Park Mode, based on Endpoint Response and Residual Transfer State

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	
IN	DATA[0,1] w/Maximum Packet sized data	Not zero	Not Zero	Allowed to perform another bus transaction. ^{1, 2}
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.

Table continues on the next page...

Table 57-42. Actions for Park Mode, based on Endpoint Response and Residual Transfer State (continued)

	DATA[0,1] w/short packet	Don't care	Don't care	Retire qTD and move to next QH.
	NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH.
OUT	ACK	Not zero	Not Zero	Allowed to perform another bus transaction. ²
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.
	NYET, NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not Zero	Not Zero	Allowed to perform another bus transaction. ²
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

1. The host controller may continue to execute bus transactions from the current high-speed queue head (if *PM-Count* is not equal to zero), if a PID mismatch is detected (for example expected DATA1 and received DATA0, or visa-versa).
2. This specification does not *require* that the host controller execute another bus transaction when *PM-Count* is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

57.4.3.10.4 Write Back qTD

This state is entered from the Execute Transaction state when the *Active* bit is set to zero.

The source data for the write-back is the transfer results area of the queue head overlay area (see [Table 57-42](#)).

The host controller uses the *Current qTD Pointer* field as the target address for the qTD.

The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include *Total Bytes to Transfer*, *Cerr*, and *Status*.

The duration of this state depends on when the qTD write-back is committed.

57.4.3.10.5 Follow Queue Head Horizontal Pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the *Active* bit is one on exit from the Execute Transaction state, or
- When the host controller exits the Write Back qTD state, or
- If the Advance Queue state fails to advance the queue because the target qTD is not active, or
- If the *Halted* bit is one on exit from the Fetch QH state.

There is no functional requirement that the host controller wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

57.4.3.10.6 Buffer Pointer List Use for Data Streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be *virtually contiguous*.

This means: if the buffer spans more than one physical page, it must obey the following rules (the figure below illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4 K chunk beyond the first page, each buffer portion matches to a full 4 K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20 K bytes. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16 Kbyte buffer with any starting buffer alignment.

The host controller uses the field *C_Page* field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing *C_Page* and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the *Bytes to Transfer* field.

The following figure illustrates a nominal example of how System software would initialize the buffer pointers list and the *C_Page* field for a transfer size of 16383 bytes. *C_Page* is set to zero. The upper 20-bits of Page 0 references the start of the physical page. *Current Offset* (the lower 12-bits of queue head Dword 7) holds the offset in the page for example 2049 (for example 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4 K page.

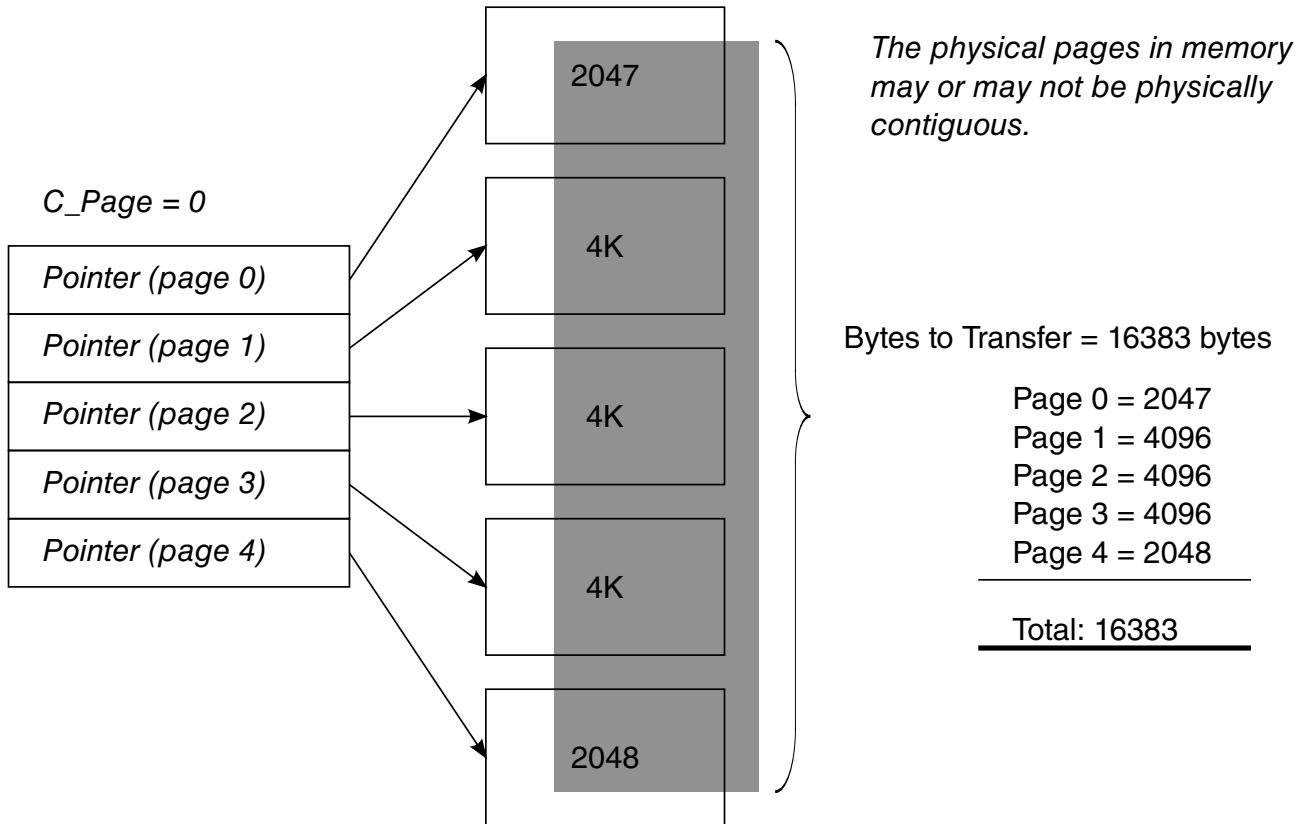

Figure 57-18. Example Mapping of qTD Buffer Pointers to Buffer Pages

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because *C_Page* is set to zero) and concatenates the *Current Offset* field. The 512 bytes are moved during the transaction, the *Current Offset* and *Total Bytes to Transfer* are adjusted by 512 and written back to the queue head working area.

During the 4th transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller increments *C_Page* (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4th transaction, the active page pointer is the page 1 pointer and *Current Offset* has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is *C_Page*) when necessary. The three conditions for how the host controller handles *C_Page*:

- The current transaction does not span a page boundary. The value of *C_Page* is not adjusted by the host controller.

- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (that is the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment *C_Page* before writing back status for the transaction.

NOTE

The only valid adjustment the host controller may make to *C_Page* is to increment by one.

57.4.3.10.7 Adding Interrupt Queue Heads to the Periodic Schedule

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate.

System software sets a bit in a queue head's *S-Mask* to indicate which micro-frame within 1 msec period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have *S-Mask* set to a non-zero value. An *S-mask* with zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and *S-Mask* values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in the following table.

Table 57-43. Example Periodic Reference Patterns for Interrupt Transfers with 2ms Poll Rate

Frame # Reference Sequence	Description
0, 2, 4, 6, 8, and so on <i>S-Mask</i> = 01h	A queue head for the <i>bInterval</i> of 2 msec (16 micro-frames) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the <i>S-Mask</i> field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during micro-frame 0 of the frame.
0, 2, 4, 6, 8, and so on <i>S-Mask</i> = 02h	Another example of a queue head with a <i>bInterval</i> of 2 msec is linked into the periodic frame list at exactly the same interval as the previous example. However, the <i>S-Mask</i> is set to 02h indicating that the transaction for the endpoint should be executed on the bus during micro-frame 1 of the frame.

57.4.3.10.8 Managing Transfer Complete Interrupts from Queue Heads

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an *Interrupt on Complete (IOC)* bit set to one, or whenever a transfer (qTD) completes with a short packet.

If system software needs multiple qTDs to complete a client request (that is like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

57.4.3.11 Ping Control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints.

Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The *Status* field has a *Ping State* bit, which the host controller uses to determine the *next* actual PID it uses in the next transaction to the endpoint (see the table below).

The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt and
- *EPS* field equals High-Speed and
- *PIDCode* field equals OUT

The following table illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

Table 57-44. Ping Control State Transition Table

Event	Host	Device	Next
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr ¹	Do Ping
Do Ping	PING	Stall	N/C ² Do
OUT	OUT	Nak	Do Ping
Do OUT	OUT	Nyet	Do Ping

Table continues on the next page...

Table 57-44. Ping Control State Transition Table (continued)

Do OUT	OUT	Ack	Do OUT
Do OUT	OUT	XactErr ¹	Do Ping
Do OUT	OUT	Stall	N/C ²

1. Transaction Error (XactErr) is any time the host misses the handshake.
2. No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (for example Active set to zero and Halt set to one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to Do Ping. The Ping State bit has the following encoding:

Table 57-45. Ping State bit Encoding

Value	Meaning
0B	Do OUT The host controller uses an OUT PID during the next bus transaction to this endpoint.
1B	Do Ping The host controller uses a PING PID during the next bus transaction to this endpoint.

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (that is start in *Do OUT* when we don't know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

57.4.3.12 Split Transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs.

This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol.

Refer to USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.

The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see [Split Transaction Isochronous Transfer Descriptor \(siTD\)](#)). Control, Bulk and Interrupt are managed using the queuing data structures (see [Queue Head](#)). The interface data structures need to be programmed with the device address and the Transaction Translator number of the USB 2.0 Hub operating as the Low-/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

57.4.3.12.1 Split Transactions for Asynchronous Transfers

A queue head in the asynchronous schedule with an *EPS* field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head.

All full-speed bulk and full-, low-speed control are managed through queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit (*SplitXState*) to Do-Start-Split. Finally, if the endpoint is a control endpoint, then system software must set the *Control Transfer Type (C)* bit in the queue head to one. If this is not a control transfer type endpoint, the *C* bit must be initialized by software to be zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the *C* bit is zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the *C* bit is one, the split transaction token's ET field is set to indicate a control endpoint. Refer to Chapter 8 of USB Specification Revision 2.0 for details.

Figure 57-19. Host Controller Asynchronous Schedule Split-Transaction State Machine

57.4.3.12.1.1 Asynchronous - Do Start Split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the Do Complete Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller executes a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and *PidCode* indicates an IN or OUT transaction, then the host controller reloads the error counter (*CErr*). If it is a successful bus transaction and the *PidCode* indicates a SETUP, the host controller does not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements *Cerr* and proceeds to the next queue head in the asynchronous schedule.

57.4.3.12.1.2 Asynchronous - Do Complete Split

This state is entered from the Do Start Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller executes a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's *PidCode* indicates an IN or OUT, the host controller reloads the error counter (*CErr*). When a Nyet handshake is received for a complete-split bus transaction where the queue head's *PidCode* indicates a SETUP, the host controller must not adjust the value of *CErr*.

Independent of *PIDCode*, the following responses have the effects:

- Transaction Error (XactErr). Timeout or data CRC failure, and so on. The error counter (*Cerr*) is decremented by one and the complete split transaction is *immediately* retried (if possible). If there is not enough time in the micro-frame to execute the retry, the host controller **MUST** ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to

accomplish this behavior is to not advance the asynchronous schedule. When the host controller returns to the asynchronous schedule in the next micro-frame, the first transaction from the schedule is the retry for this endpoint.

If *Cerr* went to zero, the host controller must halt the queue.

- **NAK.** The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the *PidCode* is a SETUP, then the Nak response is a protocol error. The *XactErr* status bit is set to one and the *CErr* field is decremented.
- **STALL.** The target endpoint responded with a STALL handshake. The host controller sets the *halt* bit in the status byte, retires the qTD but does not attempt to advance the queue.

If the *PidCode* indicates an IN, then any of following responses are expected:

- **DATA0/1.** On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is *good*, the host controller advances the state of the transfer, for example move the data pointer by the number of bytes received, decrement *BytesToTransfer* field by the number of bytes received, and toggle the *dt* bit. The host controller then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the *PidCode* indicates an OUT/SETUP, then any of following responses are expected:

- **ACK.** The target endpoint accepted the data, so the host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount and the data toggle bit (*dt*) is toggled. The host controller then exit this state.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).

57.4.3.12.2 Split Transaction Interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed through the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule.

Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller visits a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the *execution* phase are different (that is takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, and so on, occurs as defined in [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#), but only occurs on the completion of a split transaction.

57.4.3.12.2.1 Split Transaction Scheduling Mechanisms for Interrupt

Full- and low-speed Interrupt queue heads have an *EPS* field indicating full- or low-speed and have a non-zero *S-mask* field.

The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each endpoint occurs. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit micro-frames, or the data or response information in the pipeline is lost.

The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The S and ^CX labels indicate micro-frames where software can schedule start-splits and complete splits (respectively).

Figure 57-20. Split Transaction, Interrupt Scheduling Boundary Conditions

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in micro-frame 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

The figure below illustrates the general layout of the periodic schedule.

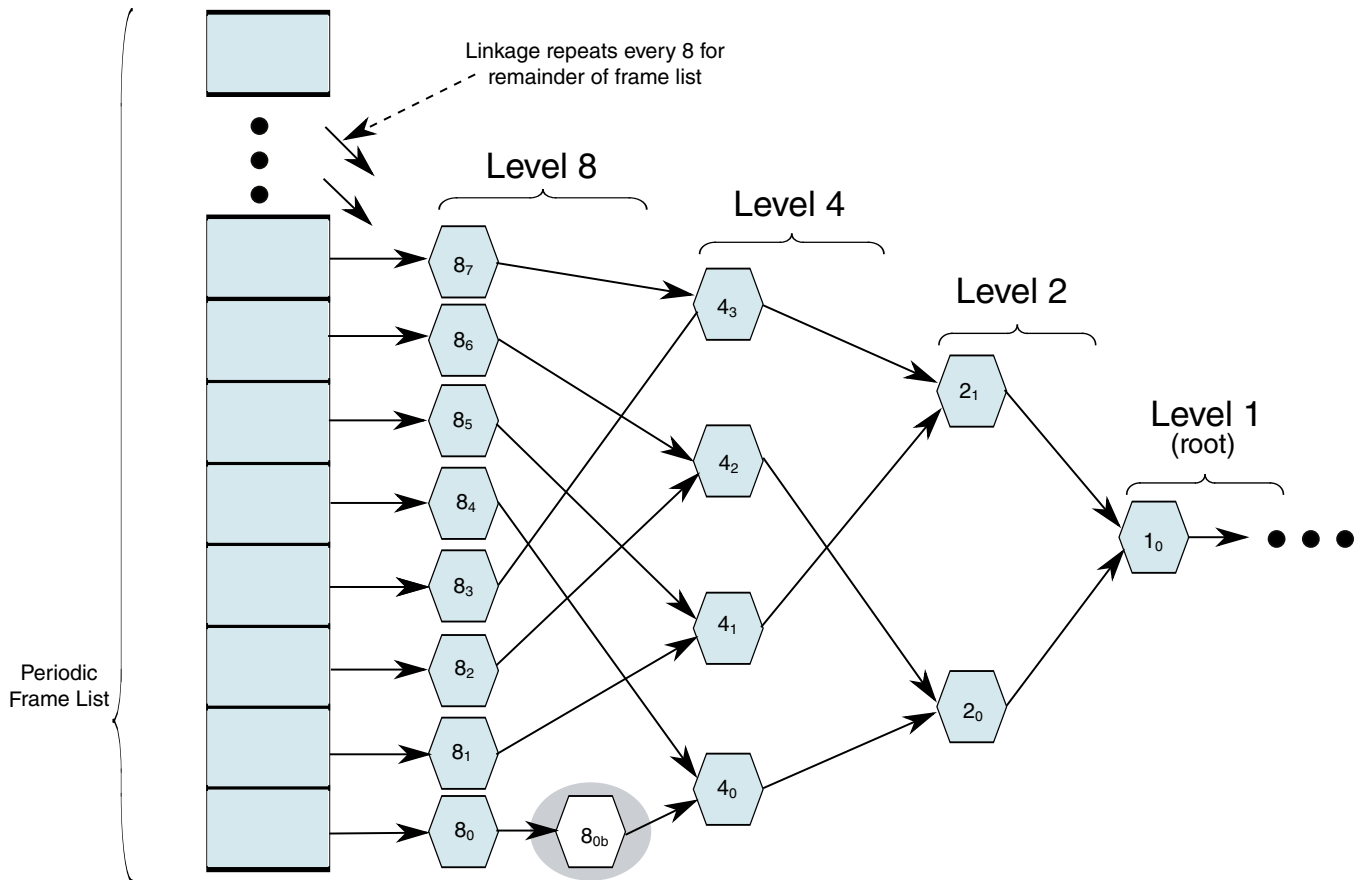

Figure 57-21. General Structure of EHCI Periodic Schedule Utilizing Interrupt Spreading

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a 2^N poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if 8_{0b} where such an endpoint. Without additional support on the interface, to get 8_{0b} reachable at the correct time, software would have to link 8₁ to 8_{0b}. It would then have to move 4₁ and everything linked after into the same path as 4₀. This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. [Host Controller Operational Model for FSTNs](#) defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol:

- *SplitXState*. This is single bit residing in the *Status* field of a queue head (see [Table 57-22](#)). This bit is used to track the current state of the split transaction.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to [Figure 57-20](#), case one, the *S-mask* would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Start, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to [Figure 57-20](#), case one, the *C-mask* would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Complete, and the current micro-frame as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between *H-Frames* and *B-Frames* is correctly performed when setting bits in *S-mask* and *C-mask*

57.4.3.12.2.2 Host Controller Operational Model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (that is boundary cases 2a through 2c).

An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see [siTD Back Link Pointer](#)).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

The four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to zero.

- A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to one.
- Host controller FSTN traversal rules.

When the host controller encounters an FSTN during micro-frames 2 through 7 it simply follows the node's *Normal Path Link Pointer* to access the next schedule data structure.

NOTE

The FSTN's *Normal Path Link Pointer.T-bit* may set to one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in micro-frames 0 or 1, it saves the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller's rules for how it traverses the schedule and limits which data structures is considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the micro-frame (see details in the list below).

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

- Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN's *Back Path Link Pointer*.
- Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer*.
- Do not process a QH (Queue Head) whose *EPS* field indicates a high-speed device. Simply follow its *Horizontal Link Pointer*.
- When a QH's *EPS* field indicates a Full/Low-speed device, the host controller considers only it for execution if its *SplitXState* is DoComplete (note: this applies whether the *PID Code* indicates an IN or an OUT). See [Execute Transaction](#) and [Tracking Split Transaction Progress for Interrupt Transfers](#) for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction.
 - The host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See [Periodic Isochronous - Do Complete Split](#) for special handling when in *Recovery Path* mode.
- Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The

host controller must clear the context of executing a *Recovery Path* when it restores schedule traversal to the *Save-Place* FSTN's *Normal Path Link Pointer*.

- If the host controller determines that there is not enough time left in the micro-frame to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive micro-frame, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in the following figure.

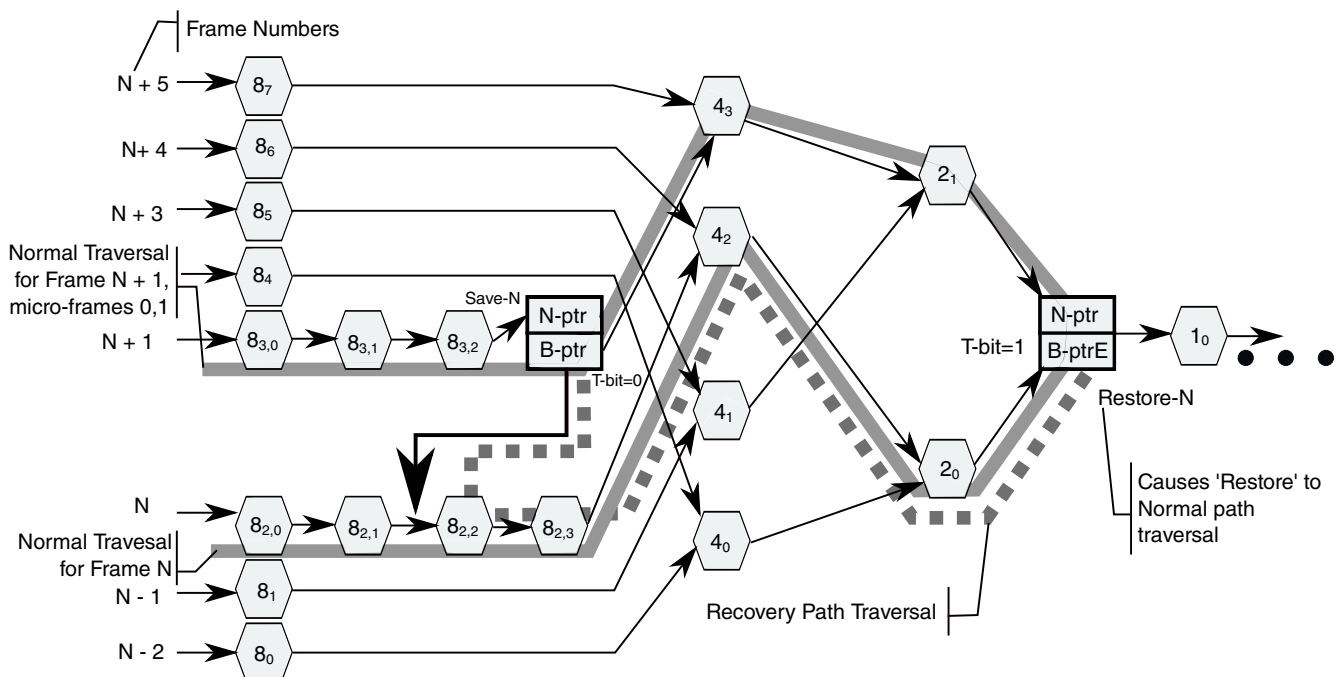

Figure 57-22. Example Host Controller Traversal of Recovery Path via FSTNs

In frame N+1 (micro-frames 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in *Recovery Path* mode (the recovery path is annotated in the figure above with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to one (definition of a Restore indicator), so the host controller exits *Recovery Path* mode by clearing the internal *Recovery Path* mode flag and commences (restores) schedule traversal using the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* (for example Save-N.Normal Path Link Pointer). The nodes traversed during these micro-frames include: {8_{3,0}, 8_{3,1}, 8_{3,2}, Save-A, 8_{2,2}, 8_{2,3}, 4₂,

2_0 , Restore-N, 4_3 , 2_1 , Restore-N, $1_0 \dots$ }. The nodes on the recovery-path are in bold. In frame N (micro-frames 0-7), for this example, the host controller traverses all of the schedule data structures utilizing the *Normal Path Link Pointers* in any FSTNs it encounters. This is because the host controller has not yet encountered a *Save-Place* FSTN so it not executing in *Recovery Path* mode. When it encounters the *Restore* FSTN, (Restore-N), during micro-frames 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (that is normal schedule traversal). This is because the host controller must use a Restore FSTN's *Normal Path Link Pointer* when not executing in a *Recovery-Path* mode. The nodes traversed during frame N include: $\{8_{2,0}$, $8_{2,1}$, $8_{2,2}$, $8_{2,3}$, 4_2 , 2_0 , Restore-N, $1_0 \dots\}$.

In frame N+1 (micro-frames 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these micro-frames include: $\{8_{3,0}$, $8_{3,1}$, $8_{3,2}$, Save-A, 4_3 , 2_1 , Restore-N, $1_0 \dots\}$.

57.4.3.12.2.3 Software Operational Model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse.

When using FSTNs, system software must adhere to the following rules:

- Each *Save-Place* indicator requires a matching *Restore* indicator.
 - The *Save-Place* indicator is an FSTN with a valid *Back Path Link Pointer* and *T-bit* equal to zero.
 - *Back Path Link Pointer.Type* field must be set to indicate the referenced data structure is a queue head. The *Restore* indicator is an FSTN with its *Back Path Link Pointer.T-bit* set to one.
 - A *Restore* FSTN may be matched to one or more *Save-Place* FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a *Restore* FSTN at the beginning of this list in order to match all possible *Save-Place* FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more *Save-Place* FSTNs are used, then System Software must ensure the *Restore* FSTN's *Normal Path Link Pointer's T-bit* is set to one, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a *Restore* FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that *Recovery Path* mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A *Save-Place* FSTN's *Back Path Link Pointer* must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list

location. In other words, if the *Save-Place* FSTN is reachable from frame list offset N, then the FSTN's *Back Path Link Pointer* must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one *Save-Place* FSTN reachable in any single frame. Note there is times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth re-balance causes system software to move the *Save-Place* FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

57.4.3.12.2.4 Tracking Split Transaction Progress for Interrupt Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost.

For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline.

When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets one of the *C-prog-mask* bits for each complete-split executed. The bit position is determined by the micro-frame number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a

complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.

- *FrameTag*. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame* number) when the next complete split must be executed.
- *S-bytes*. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

57.4.3.12.2.5 Split Transaction Execution State Machine for Interrupt

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence.

Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- *cMicroFrameBit* is a single-bit encoding of the current micro-frame number. It is an eight-bit value calculated by the host controller at the beginning of every micro-frame. It is calculated from the three least significant bits of the *FRINDEX* register (that is, $cMicroFrameBit = (1 \text{ shifted-left}(FRINDEX[2:0]))$). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current micro-frame number. For example, if the current micro-frame is 0, then *cMicroFrameBit* will equal 00000001b. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start- or complete-split transaction for the current micro-frame.

The following figure illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at *Do_Start* and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to *Do_Complete*. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the *Do_Complete* state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the *Do_Complete* state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (for example, after the host tries the same transaction three times, and each

encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

Figure 57-23. Split Transaction State Machine for Interrupt

See Previous Section for the frame tag management rules.

Periodic Interrupt - Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head *StartXState* bit. This state is entered from the Do_Complete Split state only after the split transaction is complete. This occurs when one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- **NAK.** A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- **ACK.** An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- **DATA 0/1.** Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- **ERR.** The transaction on the low-/full-speed link below the transaction translator had a failure (for example, timeout, bad CRC, etc.).
- **NYET (and Last).** The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section [Periodic Isochronous - Do Complete Split](#) for the definition of 'Last'.

Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it performs the following test to determine whether to execute a start-split.

- *QH.S-mask* is bit-wise anded with *cMicroFrameBit*.

If the result is non-zero, then the host controller will issue a start-split transaction. If the *PIDCode* field indicates an IN transaction, the host controller must zero-out the *QH.S-bytes* field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into *QH.FrameTag* field (see Section), set *C-prog-mask* to zero (00h), and exits this state. Note that the host controller must not adjust the value of *CErr* as a result of completion of a start-split transaction.

Periodic Interrupt - Do Complete Split

This state is entered unconditionally from the Do Start Split state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- Test A. *cMicroFrameBit* is bit-wise anded with *QH.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame.
- Test B. *QH.FrameTag* is compared with the current contents of *FRINDEX[7:3]*. An equal indicates a match.
- Test C. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)
Begin
-- Return values:
-- TRUE - no error
-- FALSE - error
--
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous micro-frame. So,
-- if the
-- 'previous bit' is set in C-mask, check C-prog-mask to
-- make sure it
-- happened.
If (previousBit bitAND QH.C-mask) then
    If not(previousBit bitAND QH.C-prog-mask) then
        rvalue = FALSE;
    End if
End If
-- If the C-prog-mask already has a one in this bit position,
```

USB Operation Model

```
-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
  rvalue = FALSE;
End if
return (rvalue)
End Algorithm
```

- Test D. Check to see if a start-split should be executed in this micro-frame. Note this is the same test performed in the Do Start Split state (see Section [Periodic Isochronous - Do Start Split](#)). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a *Recovery Path* mode, it means a start-split should occur in this micro-frame. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. On completion of the complete-split transaction, the host controller records the result of the transaction in the queue head and sets *QH.FrameTag* to the expected *H-Frame* number (see Section). The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the *CErr* will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the Last complete split can be performed by XOR *QH.C-mask* with *QH.C-prog-mask*. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the *XactErr* status bit is set to a one and the *CErr* field is decremented.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask* and *FrameTag*) and stay in this state. The host controller must not adjust *CErr* on this response.

- Transaction Error (XactErr). Timeout, data CRC failure, etc. The *CErr* field is decremented and the *XactErr* bit in the *Status* field is set to a one. The complete split transaction is *immediately* retried (if *CErr* is non-zero). If there is not enough time in the micro-frame to complete the retry and the endpoint is an IN, or *CErr* is decremented to a zero from a one, the queue is halted. If there is not enough time in the micro-frame to complete the retry and the endpoint is an OUT and *CErr* is not zero, then this state is exited (that is, return to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section full- and low-speed Interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.
- ACK. This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount. And the data toggle bit (*dt*) is toggled. The host controller will then exit this state for this queue head. The host controller must reload *CErr* with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).
- MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in *QH.S-bytes*. The host controller must not adjust *CErr* on this response.
- DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in *QH.S-bytes*. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload *CErr* with maximum value on this response.

- **ERR.** There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, *Cerr* is decremented, the state of the transfer is not advanced, and this state is exited.
- **STALL.** The queue is halted (an exit condition of the Execute Transaction state). The status field bits: *Active* bit is set to zero and the *Halted* bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. The table below lists the possible combinations and the appropriate action.

Table 57-46. Interrupt IN/OUT Do Complete Split State Execution Criteria

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current micro-frame. Host controller should continue walking the schedule.
A not(C)	If <i>PIDCode</i> = IN Halt QHD If <i>PIDCode</i> = OUT Retry start-split	Progress bit check failed. These means a complete-split has been missed. There is the possibility of lost data. If <i>PIDCode</i> is an IN, then the Queue head must be halted. If <i>PIDCode</i> is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> . In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one.
A not(B) C	If <i>PIDCode</i> = IN Halt QHD If <i>PIDCode</i> = OUT Retry start-split	<i>QH.FrameTag</i> test failed. This means that exactly one or more <i>H-Frames</i> have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If <i>PIDCode</i> is an IN, then the Queue head must be halted. If <i>PIDCode</i> is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> . In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one.
A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.
D	If <i>PIDCode</i> = IN Halt QHD If <i>PIDCode</i> = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If <i>PIDCode</i> is an IN, then the Queue head must be halted. If <i>PIDCode</i> is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> . In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one. Note: When executing in the context of a <i>Recovery Path</i> mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the

Table 57-46. Interrupt IN/OUT Do Complete Split State Execution Criteria

		normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a <i>Recovery Path</i> mode.
--	--	--

Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see [Figure 57-20](#)).
- Rule 2: If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c ([Figure 57-20](#)).
- Rule 3: If transitioning from Do_Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is not 6, or currently in Do Complete Split and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases ([Figure 57-20](#)).

57.4.3.12.2.6 Rebalancing the periodic schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation.

This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction* (*I*) bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.
- If the *Active* bit is a one and the *SplitXState* is DoStart (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is

not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed its final bus-transaction and set *Active* to a zero.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Because the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

1. Set the *Halted* bit to a one, then
2. Set the *I-bit* to a zero, then
3. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

57.4.3.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions.

This data structure uses the scheduling model of isochronous TDs (iTd, Section [Isochronous \(High-Speed\) Transfer Descriptor \(iTd\)](#)) (see Section [Managing Isochronous Transfers Using iTDs](#) for the operational model of iTDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

57.4.3.12.3.1 Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur.

The requirements described in Section [Split Transaction Scheduling Mechanisms for Interrupt](#) apply. The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The ^SX and ^CX labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

Figure 57-24. Split Transaction, Isochronous Scheduling Boundary Conditions

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to *N* complete-splits. The scheduling boundary cases are:

- *Case 1:* The entire split transaction is completely bounded by an *H-Frame*. For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.

- *Case 2a*: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame*, micro-frames 6 or 7 (*H-Frame* micro-frame 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list. (For example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see [Figure 57-25](#)). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in [Section Split Transaction Execution State Machine for Interrupt](#).
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in [Figure 57-24](#), case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Start Split, and the current micro-frame as indicated by `USB_n_FRINDEX[2:0]` is 0, then execute a start-split transaction.
- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in [Figure 57-24](#), case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do

Complete Split, and the current micro-frame as indicated by *USB_n_FRINDEX*[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.

- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN and OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. The figure below illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

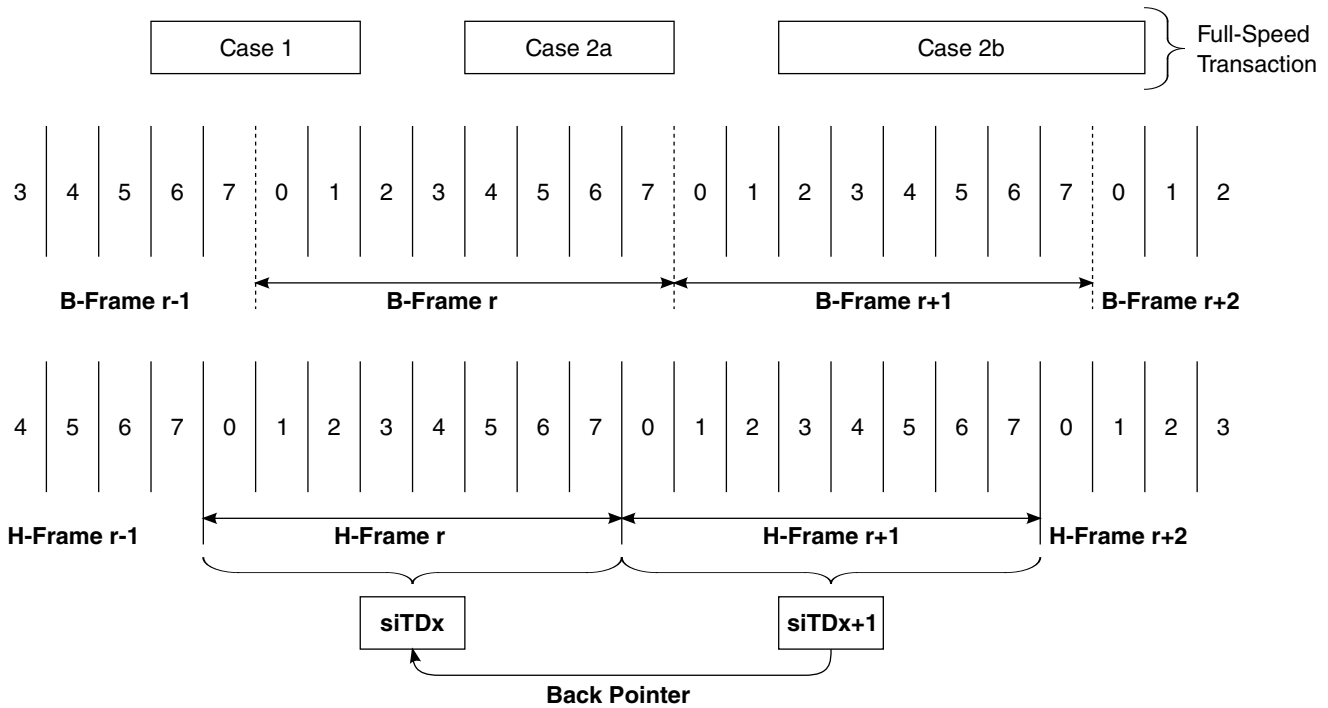

Figure 57-25. siTD Scheduling Boundary Examples

Each case is described below:

- *Case 1*: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.
- *Case 2a, 2b*: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction siTD_X is used to always issue the start-split and the first *N* complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of *H-Frame*_{Y+1}, or micro-frame 0 of *H-Frame*_{Y+2}. The complete splits are scheduled using siTD_{X+2} (not shown). The complete-splits to extract this data must use the buffer pointer from siTD_{X+1}. The only way for the host controller to reach siTD_{X+1} from *H-Frame*_{Y+2} is to use siTD_{X+2}'s back pointer. The host controller rules for when to use the back pointer are described in Section [Periodic Isochronous - Do Complete Split](#).

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, micro-frame 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of *H-Frame N* and the last complete-split would need to occur in micro-frame 1 of *H-Frame N+1*. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

57.4.3.12.3.2 Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction *N* are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields *Transaction Position (TP)* and *Transaction Count (T-count)*. If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section [Periodic Isochronous - Do Start Split](#) for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction

isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the micro-frame (`USB_n_FRINDEX[2:0]`) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section [Asynchronous - Do Complete Split](#) for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the

remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement its *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

57.4.3.12.3.3 Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section [Tracking Split Transaction Progress for Interrupt Transfers](#), plus the variable *cMicroFrameBit* defined in Section [Split Transaction Execution State Machine for Interrupt](#) to track the progress of an isochronous split transaction. The figure below illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

Figure 57-26. Split Transaction State Machine for Isochronous

57.4.3.12.3.4 Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state.

An *siTD* for a split-transaction isochronous IN is either initialized to this state, or the *siTD* transitions to this state from **Do Complete Split** when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active *siTD* in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the *siTD* will execute a start-split transaction. By definition, the host controller cannot *reach* an *siTD* at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory

buffer address for the data payload is constructed by concatenating *siTD.Current Offset* with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

T-Count is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see [Figure 57-25](#)) is used to determine the initial value of *TP*. The initial cases are summarized in the following table.

Table 57-47. Initial Conditions for OUT siTD's TP and T-count Fields

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated.

The table below illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

Table 57-48. Transaction Position (TP)/Transaction Count (T-Count) Transition Table

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when <i>T-count</i> starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when <i>T-count</i> starts at greater than 2.
MID	!=1	MID	<i>TP</i> stays at MID while <i>T-count</i> is not equal to 1 (that is, greater than 1). This case can occur for any of the scheduling boundary cases where the <i>T-count</i> starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the <i>T-count</i> starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in [Table 57-48](#).

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count* and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in Section [Split Transaction for Isochronous - Processing Examples](#).

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit()* algorithm defined in [Periodic Isochronous - Do Complete Split](#) can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

57.4.3.12.3.5 Periodic Isochronous - Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint.

This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- Test B. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section [Periodic Isochronous - Do Complete Split](#)). The sequence in which this test is applied depends on the current value of `USB_n_FRINDEX[2:0]`. If `USB_n_FRINDEX[2:0]` is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

Algorithm Boolean CheckPreviousBit(*siTD.C-prog-mask*, *siTD.C-mask*, *cMicroFrameBit*)

Begin

```

Boolean rvalue = TRUE;
previousBit = cMicroFrameBit rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates whether there was an intent
-- to send a complete split in the previous micro-frame. So, if the
-- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
-- happened.
if previousBit bitAND siTD.C-mask then
    if not (previousBit bitAND siTD.C-prog-mask) then
        rvalue = FALSE
    End if
End if
Return rvalue

```

End Algorithm

If Test A is true and `USB_n_FRINDEX[2:0]` is zero or one, then this is a case 2a or 2b scheduling boundary (see [Figure 57-24](#)). See Section [Periodic Isochronous - Do Complete Split](#) for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer*,
- Adjust *siTD.Current Offset* by the number of bytes received,

- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives and MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, etc. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the *Active* bit is set to zero.
- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section [Periodic Isochronous - Do Complete Split](#) . If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled complete-splits with NYETs,

meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing *C-mask* with *C-prog-mask*. A zero result indicates that all complete-splits have been executed.

- **MDATA (and Last).** See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-masks* incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- **NYET (and not Last).** See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- **MDATA (and not Last).** The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame *X* to *X+1* and during micro-frame *X*, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame *X*. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the *Active* bit to a zero.

57.4.3.12.3.6 Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see [Figure 57-24](#)) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. The table below enumerates the transaction state fields.

Table 57-49. Summary siTD Split Transaction State

Buffer State	Status	Execution Progress
Total Bytes To Transfer	All bits in the status field	C-prog-mask
P (page select)		
Current Offset		
TP (transaction position)		
T-count (transaction count)		

NOTE

TP and *T-count* are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the *siTD.Back Pointer* field to reference a valid siTD and will have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer*

field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is Do Complete Split.

- When *cMicroFrameBit* is a 1h and the *siTDX.Back Pointer.T-bit* is a zero, or
- If *cMicroFrameBit* is a 2h and *siTDX.S-mask[0]* is a zero

When either of these conditions apply, then the host controller must use the transaction state from *siTD_{X-1}*.

In order to access *siTD_{X-1}*, the host controller reads on-chip the siTD referenced from *siTD_X.Back Pointer*.

The host controller must save the entire state from *siTD_X* while processing *siTD_{X-1}*. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers*.

If *siTD_{X-1}* is active (*Active* bit is a one and *SplitXStat* is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see [Table 57-49](#)) of *siTD_{X-1}* is appropriately advanced based on the results and written back to memory. If the resultant state of *siTD_{X-1}*'s *Active* bit is a one, then the host controller returns to the context of *siTD_X*, and follows its next pointer to the next schedule item. No updates to *siTD_X* are necessary.

If *siTD_{X-1}* is active (*Active* bit is a one and *SplitXStat* is Do Start Split), then the host controller must set *Active* bit to a zero and *Missed Micro-Frame* status bit to a one and the resultant status written back to memory.

If *siTD_{X-1}*'s *Active* bit is a zero, (because it was zero when the host controller first visited *siTD_{X-1}* via *siTD_X*'s back pointer, it transitioned to zero as a result of a detected error, or the results of *siTD_{X-1}*'s complete-split transaction transitioned it to zero), then the host controller returns to the context of *siTD_X* and transitions its *SplitXState* to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if *cMicroframeBit* is a 1b and *siTD_X.S-mask[0]* is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of *siTD_X*, then follows *siTD_X.Next Pointer* to the next schedule item. If the criterion is not met, the host controller simply follows *siTD_X.Next Pointer* to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of *siTD_{X-1}* will have its *Active* bit set to zero when the host controller returns

to the context of $siTD_x$. Also, note that software should not initialize an siTD with *C-mask* bits 0 and 1 set to a one and an *S-mask* with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

57.4.3.12.3.7 Split Transaction for Isochronous - Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines.

The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the Execute Transaction queue head traversal state machine (see [Figure 57-17](#)).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, the table below illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

Table 57-50. Example Case 2a - Software Scheduling siTDs for an IN Endpoint

siTDX		Micro-Frames								Initial
#	Masks	0	1	2	3	4	5	6	7	SplitXState
X	S-Mask	-	-	-	-	1	-	-	-	Do Start Split
	C-Mask	1	1	-	-	-	-	1	1	
X+1	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Because this is the case-2a frame-wrap case, *S-masks* of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and *C-mask* value of C3h (one-bits in micro-frames 0,1, 6 and 7). Additionally, software ensures that the *Back Pointer* field of each siTD references the appropriate siTD data structure (and the *Back PointerT-bits* are set to zero).

The initial *SplitXState* of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is Do Start Split. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to Do Complete Split. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has its *SplitXState* initialized to Do Complete Split. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, micro-frame 0, the host controller detects that siTD_{X+1}'s *Back Pointer.T-bit* is a zero, saves the state of siTD_{X+1} and fetches siTD_X. It executes the complete split transaction using the transaction state of siTD_X. If the siTD_X split transaction is complete, siTD's *Active* bit is set to zero and results written back to siTD_X. The host controller retains the fact that siTD_X is retired and transitions the *SplitXState* in the siTD_{X+1} to Do Start Split. At this point, the host controller is prepared to execute the start-split for siTD_{X+1} when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section [Periodic Isochronous - Do Complete Split](#)), that is, before all the scheduled complete-splits have been executed, the host controller will transition *siTD_X.SplitXState* to Do Start Split early and naturally skip the remaining scheduled complete-split transactions. For this example, siTD_{X+1} does not receive a DATA0 response until *H-Frame* X+2, micro-frame 1.

During *H-Frame* X+2, micro-frame 0, the host controller detects that siTD_{X+2}'s *Back Pointer.T-bit* is a zero, saves the state of siTD_{X+2} and fetches siTD_{X+1}. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the *Active* bit. The host controller returns to the context of siTD_{X+2}, and traverses its next pointer without any state change updates to siTD_{X+2}. S

During *H-Frame* X+2, micro-frame 1, the host controller detects siTD_{X+2}'s *S-mask[0]* is a zero, saves the state of siTD_{X+2} and fetches siTD_{X+1}. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of siTD_{X+2} and changes its *SplitXState* to Do Start Split. At this point, the host controller is prepared to execute start-splits for siTD_{X+2} when it reaches micro-frame 4.

57.4.3.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports.

When the schedules are enabled, the EHCI host controller will access the schedules in main memory each micro-frame. This constant pinging of main memory is known to create ARM platform power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the ARM platform, based on recent history usage. In the more aggressive power saving modes, the ARM platform can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the ARM platform power management software can detect this activity over time and inhibit the transition of the ARM platform into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they access their memory-based schedules keeps the ARM platform power management software from placing the ARM platform into its lowest power savings state.

USB Host controllers don't access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the ARM platform power management to get the ARM platform into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the ARM platform to reach its low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the ARM platform will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing its shared memory based data structures (schedule lists or otherwise).

57.4.3.14 Port Test Modes -Host Operational Model

EHCI host controllers must implement the port test modes Test J_State, Test K_State, Test_Packet, Test Force_Enable, and Test SEO_NAK as described in the USB Specification Revision 2.0.

The system is only allowed to test ports that are owned by the EHCI controller (for example, *CF-bit* is a one and *PortOwner* bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the *CF-bit* in the USB_n_CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate USB_n_PORTSC register to a one.
- Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
- Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test_Force_Enable, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting *HCRreset* to a one.

57.4.3.15 Interrupts-Host Operational Model

The EHCI Host Controller hardware provides interrupt capability based on a number of sources.

There are several general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions),
- Host controller events (Port change events, etc.), and
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR, see Section [Interrupt Enable Register \(USB_nUSBINTR\)](#)).

Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight micro-frames. This means that the host controller will not generate interrupts any more frequently than once every eight micro-frames.

Section [Host System Error](#) details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, ARM platform control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to read the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINTR register, see Section [Interrupt Enable Register \(USB_nUSBINTR\)](#)) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register (Section [USB Status Register \(USB_nUSBSTS\)](#)) from a one to a zero.

57.4.3.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

57.4.3.15.1.1 Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully.

The table below lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

Table 57-51. Summary of Transaction Errors

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1 ¹
Timeout	-1	XactErr set to a one.	1 ¹
Bad PID ²	-1	XactErr set to a one.	1 ¹
Babble	N/A	Section Serial Bus Babble	1
Buffer Error	N/A	Section Data Buffer Error	

1. If occurs in a queue head, then *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted, see [Halting a Queue Head](#).
2. The host controller received a response from the device, but it could not recognize the PID as a valid PID.

57.4.3.15.1.2 Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*.

When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see [Halting a Queue Head](#)). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the USB_n_USBSTS register is set to a one and if the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

NOTE

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

57.4.3.15.1.3 Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction.

This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

57.4.3.15.1.4 USB Interrupt (Interrupt on Completion (IOC))

Transfer Descriptors (iTDS, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USB_n_USBSTS register to be set to a one.

In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USB_n_USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USB_n_USBSTS register is also set to a one.

57.4.3.15.1.5 Short Packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USB_n_USBSTS register is set to a one.

If the *USB Interrupt Enable* bit is set in the USB_n_USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

57.4.3.15.2 Host Controller Event Interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section [Interrupt on Async Advance](#)).

57.4.3.15.2.1 Port Change Events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one.

If the *Port Change Interrupt Enable* bit in the USB_n_USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

57.4.3.15.2.2 Frame List Rollover

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs.

If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USB.USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USB.USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

57.4.3.15.2.3 Interrupt on Async Advance

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USB.USBCMD register.

If it is a one, it sets the *Interrupt on Async Advance* bit in the USB.USBSTS register to a one. If the *Interrupt on Async Advance Enable* bit in the USB.USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section [Removing Queue Heads from Asynchronous Schedule](#) .

57.4.3.15.2.4 Host System Error

The host controller is a bus master and any interaction between the host controller and the system may experience errors.

The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to continue in a coherent fashion. In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USB.USBCMD register is set to a zero.
- The following bits in the USB.USBSTS register are set:
 - *Host System Error* bit is to a one.
 - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. The following table summarizes the required actions taken on the various host errors.

Table 57-52. Summary Behavior of EHCI Host Controller on Host System Errors

Cycle Type	Master Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]
iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

NOTE

After a *Host System Error*, Software must reset the host controller through *HCRreset* in the USB.USBCMD register before re-initializing and restarting the host controller.

57.4.4 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specification. Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. <http://www.intel.com>. Device operation & On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is proprietary.

The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

57.4.4.1 Embedded Transaction Translator Function

The OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

57.4.4.1.1 Capability Registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N_TT added to USB.HCSPARAMS - Host Control Structural Parameters
- N_PTT added to USB.HCSPARAMS - Host Control Structural Parameters

57.4.4.1.2 Operational Registers

The following additions have been added to the operational registers to support the embedded TT:

- Addition of two-bit Port Speed (PSPD) to the [Port Status & Control \(USB_nPORTSC1\)](#) register.

57.4.4.1.3 Discovery-EHCI Deviation

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation.

The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in the following table.

Table 57-53. Summary of EHCI

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (ie. Split target hub)]	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (ie. Split target hub is the root hub)]

57.4.4.1.4 Data Structures

The same data structures used for FS/LS transactions through a HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator.

Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) - Async. (Bulk/Control Endpoints) Periodic (Interrupt)
 - Hub Address = 0
 - Transactions to direct attached device/hub.
 - QH.EPS = Port Speed
 - Transactions to a device downstream from direct attached FS hub.
 - QH.EPS = Downstream Device Speed

NOTE

When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

Maximum Packet Size must be less than or equal 64 or undefined behaviour may result.

2. siTD (for direct attach FS) - Periodic (ISO Endpoint)
 - All FS ISO transactions:
 - Hub Address = 0
 - siTD.EPS = 00 (full speed)
 - Maximum Packet Size must less than or equal to 1023 or undefined behaviour may result.

57.4.4.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specification. Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. <http://www.usb.org>) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

57.4.4.1.5.1 Micro- frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

57.4.4.1.5.2 Split State Machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator.

Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. The following table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 57-54. Summary of the Conditions of Handshakes¹

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

1. The un-shaded cells represent Start-Splits and the shaded cells represent Complete-Splits

57.4.4.1.5.3 Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.
- Transaction tracking for 2 data pipes.

57.4.4.1.5.3.1 USB 2.0 - 11.17.3

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

57.4.4.1.5.3.2 USB 2.0 - 11.17.4

- Transaction tracking for 2 data pipes.

57.4.4.1.5.4 Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Abort of pending start-splits
 - EOF (and not started in micro-frames 6)
 - Idle for more than 4 micro-frames
- Abort of pending complete-splits
 - EOF
 - Idle for more than 4 micro-frames
- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

57.4.4.1.5.4.1 USB 2.0 - 11.18.6.[1-2]

- Abort of pending start-splits
 - EOF (and not started in micro-frames 6)
 - Idle for more than 4 micro-frames
- Abort of pending complete-splits

- EOF
- Idle for more than 4 micro-frames

57.4.4.1.5.4.2 USB 2.0 - 11.18.[7-8]

- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

57.4.4.1.5.5 Multiple Transaction Translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N_TT field in the [Host Controller Structural Parameters \(USB_nHCSPARAMS\)](#) register.

57.4.4.2 Device Operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

57.4.4.2.1 USB_USBMODE Register

Given that the dual-role controller is initialized in neither host nor device mode, the [USB Device Mode \(USB_nUSBMODE\)](#) register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

57.4.4.2.2 Non-Zero Fields the Register File

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode .

57.4.4.2.3 SOF Interrupt

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode.

EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See [USB Status Register \(USB_nUSBSTS\)](#) and [Interrupt Enable Register \(USB_nUSBINTR\)](#) registers.

57.4.4.3 Embedded Design Interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

57.4.4.3.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 Mhz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

57.4.4.4 Miscellaneous variations from EHCI

57.4.4.4.1 Programmable Physical Interface Behaviour

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the [Port Status & Control \(USB_nPORTSC1\)](#) register providing a capability that is not defined by EHCI.

57.4.4.4.2 Discovery

57.4.4.4.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the [Port Status & Control \(USB_nPORTSC1\)](#) register for a duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to reset the device.
- Software shall write a '0' to reset the device after 10 ms.
 - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress, the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device is now operational and at this point the port speed has been determined.

57.4.4.4.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices.

Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - *This information is redundant with the 2-bit Port Speed indicator above.*

57.4.4.4.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI. An alternate host controller driver procedure is not necessary or supported.

57.4.5 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller.

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writable fields. The device controller must preserve the read-only fields on all data structure writes.

The figure below shows the organization of the EndPoint Queue Head.

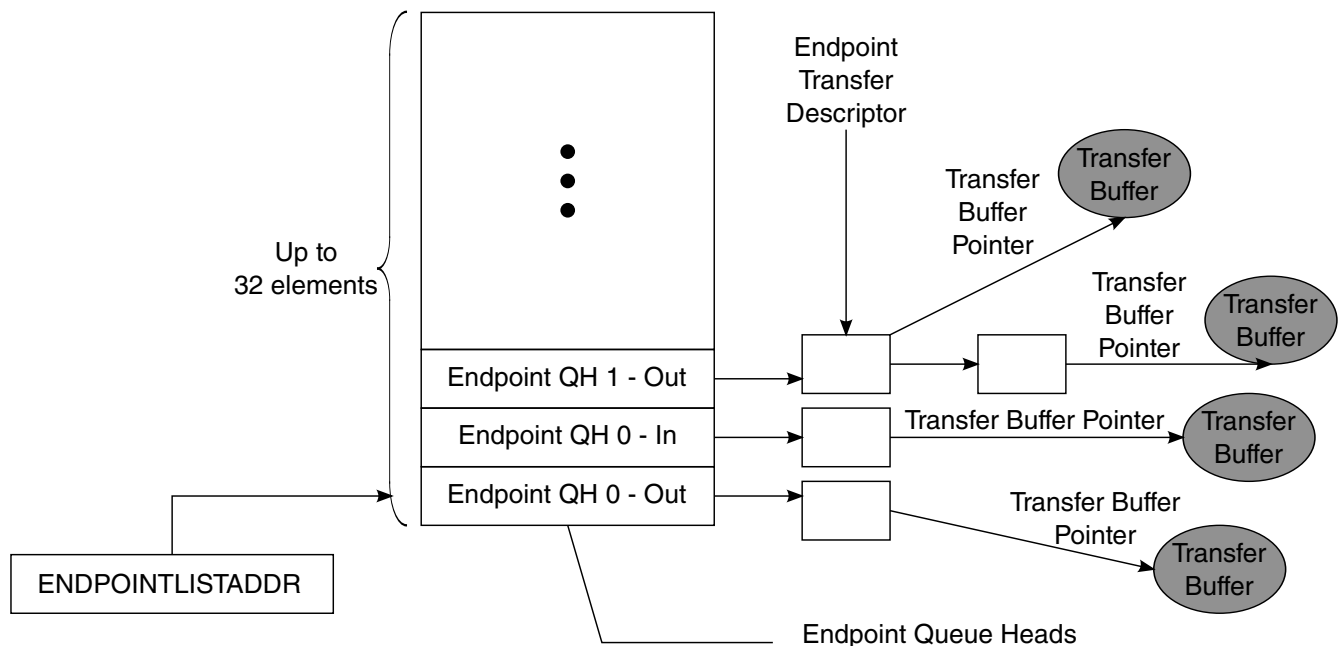

Figure 57-27. EndPoint Queue Head Organization

Endpoint queue heads are arranged in an array in a continuous area of memory pointed to by the USB.ENDPOINTLISTADDR pointer. The even -numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

NOTE

The Endpoint Queue Head List must be aligned to a 2k boundary.

57.4.5.1 Endpoint Queue Head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers for a given endpoint are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

Table 57-55. Endpoint Queue Head (dQH)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host Controller Read/Write

Host Controller Read Only

57.4.5.1.1 Endpoint Capabilities/Characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

Table 57-56 describes the endpoint capabilities.

Table 57-56. Endpoint Capabilities/Characteristics

Bit	Description
31-30	Mult. This field is used to indicate the number of packets executed per transaction description as given by the following: 00 - Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD) 01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions. NOTE: Non-ISO endpoints must set Mult="00". ISO endpoints must set Mult="01", "10", or "11" as needed.
29	Zero Length Termination Select. This bit is used to indicate when a zero length packet is used to terminate transfers where the total transfer length is a multiple of the Maximum Packet Length. This bit is not relevant for Isochronous 0 - Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default). 1 - Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28-27	Reserved. These bits reserved for future use and should be set to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	Interrupt On Setup (IOS). This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14-0	Reserved. Bits reserved for future use and should be set to zero.

57.4.5.1.2 Transfer Overlay-Endpoint Queue Head

The seven DWords in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

57.4.5.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

The following table describes the dTD Pointer.

Table 57-57. Next dTD Pointer

Bit	Description
31-5	Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved. Bit reserved for future use and should be set to zero.

57.4.5.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

The following table describes the Multiple Mode Control.

Table 57-58. Multiple Mode Control (HCCPARAMS)

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

57.4.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/received for a given transfer.

The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in section [Managing Transfers with Transfer Descriptors](#).

Table below shows the Endpoint Transfer Descriptor (dTD).

Table 57-59. Endpoint Transfer Descriptor (dTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Next Link Pointer																												0	T		
0	Total Bytes															ioc	0	MultO	0	Status

Buffer Pointer (Page 2)														Reserved																	
Buffer Pointer (Page 3)														Reserved																	
Buffer Pointer (Page 4)														Reserved																	

Host Controller Read/Write

Host Controller Read Only

The following table describes the dTD Pointer.

Table 57-60. Next dTD Pointer

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved. Bits reserved for future use and should be set to zero.
0	Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

The following table describes the dTD Token.

Table 57-61. dTD Token

Bit	Description
31	Reserved. Bit reserved for future use and should be set to zero.
30-16	<p>Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction.</p> <p>The maximum value software may store in the field is 5*4K (5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K (4000H).</p> <p>If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor.</p>

Table continues on the next page...

Table 57-61. dTD Token (continued)

	It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of <i>Maximum Packet Length</i> . If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less than <i>Maximum Packet Length</i> .
15	Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14-12	Reserved. Bits reserved for future use and should be set to zero.
11-10	Multiplier Override (MultiO). This field can be used for transmit ISO's (ie. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO. Example: if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default] Three packets are sent: {Data2(8); Data1(7); Data0(0)} if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2 Two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, software should compute MultiO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultiO should be 1. Note: Non-ISO and Non-TX endpoints must set MultiO = "00".
9-8	Reserved. Bits reserved for future use and should be set to zero.
7-0	Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are: Bit Status Field Description 7 Active. 6 Halted. 5 Data Buffer Error. 3 Transaction Error. 4, 2, 0 Reserved.

The table below describes the dTD Buffer Page Pointer List.

Table 57-62. dTD Buffer Page Pointer List

Bit	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0,11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.
1,10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

57.4.6 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus.

Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

57.4.6.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs.

Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

- Set Controller Mode in the USB.USBMODE register to device mode.

NOTE

Transitioning from host mode to device mode requires a device controller reset before modifying USB.USBMODE.

- Allocate and Initialize device queue heads in system memory.
 - Minimum: Initialize device queue heads 0 Tx & 0 Rx.

NOTE

All device queue heads for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

- For information on device queue heads, refer to section [Device Data Structures](#).
- Configure USB.ENDPOINTLISTADDR Pointer.
 - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
- Enable the microprocessor interrupt associated with the USB core.
 - Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
 - For a list of available interrupts refer to the [Interrupt Enable Register \(USB_nUSBINTR\)](#) and the [USB Status Register \(USB_nUSBSTS\)](#) register tables.
- Set Run/Stop bit to Run Mode.

- After the Run bit is set and the device is connected to a host, a Bus Reset will be issued by host downstream port. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the Port State and Control section below.

NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using `ENDPTCTRL0` register.

It is also not necessary to prime Endpoint 0 initially because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

57.4.6.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'.

After receiving a reset on the bus, the port will enter the *defaultFS* or *defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0.

The following state diagram depicts the state of a USB 2.0 device.

Figure 57-28. Device State Diagram

States *powered*, *attach*, *defaultFS/HS*, *suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

The following table describes the Device Controller State Information Bits.

Table 57-63. Device Controller State Information Bits

Bit	Register
DCSuspend	USB Status Register (USB_nUSBSTS)
USB Reset Received	USB Status Register (USB_nUSBSTS)
Port Change Detect	USB Status Register (USB_nUSBSTS)
High-Speed Port	Port Status & Control (USB_nPORTSC1)

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the USB_UOG_ENDPTCTRLx registers and initializing the associated queue heads.

57.4.6.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices.

When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the [Endpoint Status \(USB_nENDPTSTAT\)](#) register and writing the same value back to the [Endpoint Status \(USB_nENDPTSTAT\)](#) register.

Clear all the endpoint complete status bits by reading the [Endpoint Complete \(USB_nENDPTCOMPLETE\)](#) register and writing the same value back to the [Endpoint Complete \(USB_nENDPTCOMPLETE\)](#) register.

Cancel all primed status by waiting until all bits in the [Endpoint Prime \(USB_nENDPTPRIME\)](#) are 0 and then writing 0xFFFFFFFF to [Endpoint Flush \(USB_nENDPTFLUSH\)](#).

Read the reset bit in the [Port Status & Control \(USB_nPORTSC1\)](#) register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the [Port Status & Control \(USB_nPORTSC1\)](#) to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

57.4.6.2.2 Suspend/Resume

The details of suspend and resume are explained in these sections.

57.4.6.2.2.1 Suspend

Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the [Port Status & Control \(USB_nPORTSC1\)](#) is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

NOTE

Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

57.4.6.2.2 Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port.

Resume signaling is sent upstream by writing a '1' to the Resume bit in the in the [Port Status & Control \(USB_nPORTSC1\)](#) while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

NOTE

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

57.4.6.3 Managing Endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk*, *interrupt*, and *isochronous*. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The USB OTG device controller hardware supports up to 8 endpoint numbers.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. To support the 8 endpoint numbers, 16 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

57.4.6.3.1 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the USB_UOG_ENDPTCTRLx register.

Each 32-bit USB_UOG_ENDPTCTRLx is split into an upper and lower half. The lower half of USB_UOG_ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the USB_UOG_ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. The following table shows the fields and values for the Device Controller Endpoint initialization.

Table 57-64. Device Controller Endpoint Initialization

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk

Table continues on the next page...

Table 57-64. Device Controller Endpoint Initialization (continued)

	11 Interrupt
Endpoint Stall	0

57.4.6.3.2 Stalling

There are two occasions where the device controller may need to return to the host a STALL.

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the USB_UOG_ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the USB_UOG_ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

NOTE

Any write to the USB_UOG_ENDPTCTRLx register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

The following table shows the response matrix for the Device Controller Stall.

Table 57-65. Device Controller Stall Response Matrix

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL

Table continues on the next page...

Table 57-65. Device Controller Stall Response Matrix (continued)

IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET
--	-----	-------	----------------------

57.4.6.3.3 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe.

For more information on data toggle, refer to the USB 2.0 specification.

57.4.6.3.3.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the USB_UOG_ENDPTCTRLx register.

This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

57.4.6.3.3.2 Data Toggle Inhibit

NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

57.4.6.3.3.3 Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTd) for the transaction pointed to by the device queue head (dQH).

After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the USB_UOG_ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section .

57.4.6.3.3.4 Priming Receive Endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

57.4.6.4 Operational Model For Packet Transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification.

At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1

transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

57.4.6.4.1 Interrupt/Bulk Endpoint Operational Model

The behaviors of the device controller for interrupt and bulk endpoints are identical.

All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

$$N = \text{INT}(\text{Number Of Bytes}/\text{Max. Packet Length}) + 1$$

With Zero Length Termination (ZLT) = 1

$$N = \text{MAXINT}(\text{Number Of Bytes}/\text{Max. Packet Length})$$

Table 57-66. Variable Length Transfer Protocol Example (ZLT = 0)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	

Table continues on the next page...

Table 57-66. Variable Length Transfer Protocol Example (ZLT = 0) (continued)

512	256	3	256	256	0
512	512	2	512	0	

Table 57-67. Variable Length Transfer Protocol Example (ZLT = 1)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

NOTE

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. *** Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. *** Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. *** This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). *** This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

NOTE

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

57.4.6.4.1.1 Interrupt/Bulk Endpoint Bus Response Matrix

The table below shows the response matrix for Interrupt/Bulk Endpoint Bus.

Table 57-68. Interrupt/Bulk Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

NOTE

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

57.4.6.4.2 Control Endpoint Operation Model

This section details the setup phase, data phase, status phase, and the control endpoint bus response matrix.

57.4.6.4.2.1 Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

The setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted by an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in [USB Device Mode \(USB_nUSBMODE\)](#). (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

NOTE

Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting [Endpoint Setup Status \(USB_nENDPTSETUPSTAT\)](#) to determine that a setup packet was received on a particular pipe:
 - a. Write 1 to clear corresponding bit [Endpoint Setup Status \(USB_nENDPTSETUPSTAT\)](#).
 - b. Write 1 to Setup Tripwire (SUTW) in [USB Command Register \(USB_nUSBCMD\)](#) register.
 - c. Duplicate contents of dQH.SetupBuffer into local software byte array.
 - d. Read Setup TripWire (SUTW) in [USB Command Register \(USB_nUSBCMD\)](#) register. (if set - continue; if cleared - goto 2)
 - e. Write 0 to clear Setup Tripwire (SUTW) in [USB Command Register \(USB_nUSBCMD\)](#) register.
 - f. Process setup packet using local software byte array copy and execute status/handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

57.4.6.4.2.2 Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the [Endpoint Prime \(USB_nENDPTPRIME\)](#) register is zero and the associated bit in the [Endpoint Status](#)

(USB_nENDPTSTAT) register is a one. If a prime fails, ie. The **Endpoint Prime (USB_nENDPTPRIME)** bit goes to zero and the **Endpoint Status (USB_nENDPTSTAT)** bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status (**Endpoint Status (USB_nENDPTSTAT)**) to enforce data coherency with the setup packet.

NOTE

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

57.4.6.4.2.3 Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase.

The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

NOTE

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

57.4.6.4.2.4 Control Endpoint Bus Response Matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

The table below shows the response matrix for the Control Endpoint Bus.

Table 57-69. Control Endpoint Bus Response Matrix

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSEERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A

Table continues on the next page...

Table 57-69. Control Endpoint Bus Response Matrix (continued)

Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

57.4.6.4.3 Isochronous Endpoint Operational Model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes.

Real time delivery by the device controller will be accomplished by the following:

- Exactly MULT Packets per (micro) Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro) frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
 - MULT counter reaches zero.
 - Fulfillment Error [*Transaction Error* bit is set]
 - # Packets Occurred > 0 AND # Packets Occurred < MULT

NOTE

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
 - MULT counter reaches zero.
 - Non-MDATA Data PID is received**
 - ** Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
 - Overflow Error:
 - Packet received is > maximum packet length. [*Buffer Error* bit is set]
 - Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]
 - Fulfillment Error [*Transaction Error* bit is set]
 - # Packets Occurred > 0 AND # Packets Occurred < MULT
 - CRC Error [*Transaction Error* bit is set]

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

57.4.6.4.3.1 Isochronous Pipe Synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro) frame number (USB_UOG_FRINDEX register) can be used as a marker.

To cause a packet transfer to occur at a specific (micro) frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB_UOG_FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro) frame N-1 so that the device controller will execute delivery during (micro) frame N.

NOTE

Priming an endpoint towards the end of (micro) frame N-1 will not guarantee delivery in (micro) frame N. The delivery may actually occur in (micro) frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

57.4.6.4.3.2 Isochronous Endpoint Bus Response Matrix

The following table shows the response matrix for the Isochronous Endpoint Bus.

Table 57-70. Isochronous Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. BS Error = Force Bit Stuff Error

NULL Packet = Zero Length Packet

57.4.6.5 Managing Queue Heads

The following figure shows the End Point Queue Head.

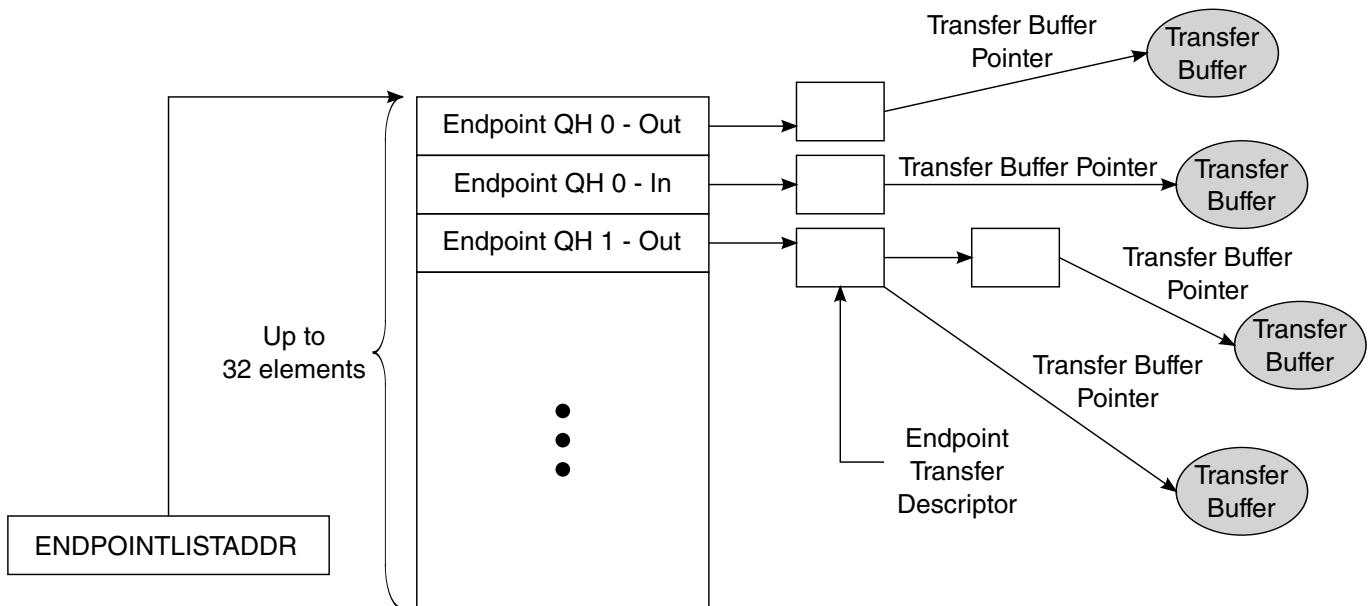

Figure 57-29. End Point Queue Head Diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTDT). An area of memory pointed to by `USB.ENDPOINTLISTADDR` contains a group of all dQH's in a sequential list as shown in [Figure 57-29](#). The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTD is retired (see section [Software Link Pointers](#)).

In addition to the current and next pointers and the dTD overlay examined in section [Operational Model For Packet Transfers](#), the dQH also contains the following parameters for the associated endpoint: Multiplier, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

57.4.6.5.1 Queue Head Initialization

One device queue head must be initialized for each active endpoint.

To initialize a device queue head:

- Write the `wMaxPacketSize` field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1,2, or 3 as required bandwidth and in conjunction with the USB Chapter 9 protocol.

NOTE

In FS mode, the multiplier field can only be 1 for ISO endpoints.

- Write the next `dTD Terminate` bit field to 1.
- Write the `Active` bit in the status field to 0.
- Write the `Halt` bit in the status field to 0.

NOTE

The DCD must only modify `dQH` if the associated endpoint is not primed and there are no outstanding `dTD`'s.

57.4.6.5.2 Operational Model For Setup Transfers

As discussed in section [Control Endpoint Operation Model](#), setup transfer requires special treatment by the DCD. A setup transfer does not use a `dTD` but instead stores the incoming data from a setup packet in an 8-byte buffer within the `dQH`.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from `dQH - RX` to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in `ENDPTSETUPSTAT`.

NOTE

- The acknowledge must occur before continuing to process the setup packet.
 - After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the `dQH - RX`. Only the local software copy should be examined.
3. Check for pending data or status `dTD`'s from previous control transfers and flush if any exist as discussed in section [Flushing/De-priming an Endpoint](#).
 4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

57.4.6.6 Managing Transfers with Transfer Descriptors**57.4.6.6.1 Software Link Pointers**

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. The following figure shows the Software Link Pointers.

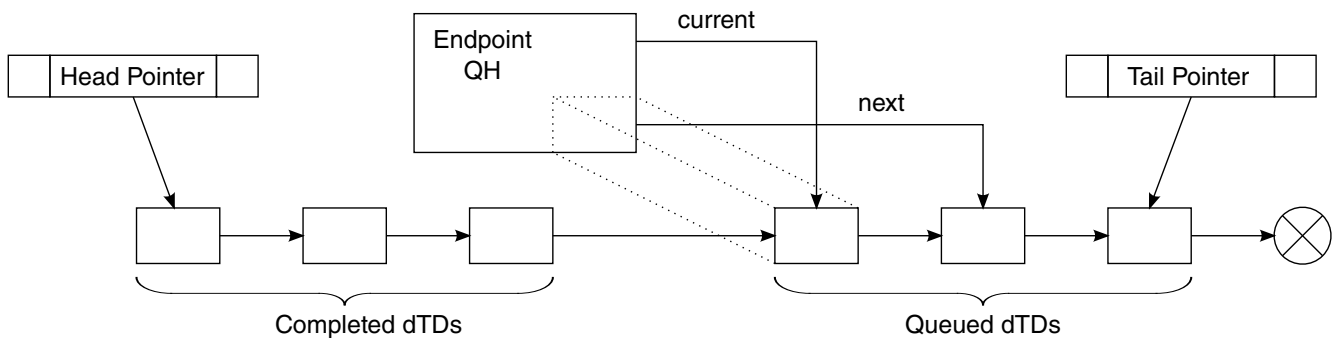

Figure 57-30. Software Link Pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

57.4.6.6.2 Building a Transfer Descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer.

Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

57.4.6.6.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty: Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding).

- Case 1: Link list is empty
 - a. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
 - b. Clear active & halt bit in dQH (in case set from a previous error).
 - c. Prime endpoint by writing 1 to correct bit position in [Endpoint Prime \(USB_nENDPTPRIME\)](#).
- Case 2: Link list is not empty
 - a. Add dTD to end of linked list.
 - b. Read correct prime bit in [Endpoint Prime \(USB_nENDPTPRIME\)](#)- if 1 DONE.
 - c. Set ATDTW bit in USBCMD register to 1.
 - d. Read correct status bit in [Endpoint Status \(USB_nENDPTSTAT\)](#). (store in tmp. variable for later)
 - e. Read ATDTW bit in USBCMD register.
 - If 0 goto 3.
 - If 1 continue to 6.
 - f. Write ATDTW bit in USBCMD register to 0.
 - g. If status bit read in (3) is 1 DONE.

h. If status bit read in (3) is 0 then Goto Case 1: Step 1.

57.4.6.6.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the [Device Error Matrix](#).

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

57.4.6.6.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer.

There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in [Endpoint Flush \(USB_nENDPTFLUSH\)](#).
2. Wait until all bits in [Endpoint Flush \(USB_nENDPTFLUSH\)](#) are '0'.

- Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read [Endpoint Status \(USB_nENDPTSTAT\)](#) to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
- Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using [Endpoint Flush \(USB_nENDPTFLUSH\)](#). A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush by repeating steps 1-3 until each endpoint is successfully flushed.

57.4.6.6.6 Device Error Matrix

The following table summarizes packet errors that are not automatically handled by the Device Controller.

Table 57-71. Device Error Matrix

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. The table below describes the errors.

Table 57-72. Error Descriptions

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length. ** This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

57.4.6.7 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

57.4.6.7.1 High-Frequency Interrupts

High frequency interrupts in particular should be handled in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

The table below describes the High frequency interrupt events.

Table 57-73. High Frequency Interrupt Events

Execution Order	Interrupt	Action
1a	USB Interrupt - USB.ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in Figure 57-29 shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt ¹ - USB.ENDPTCOMPLETE	Handle completion of dTD as indicated in Figure 57-29 shows the End Point Queue Head.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

57.4.6.7.2 Low-Frequency Interrupts

The low frequency interrupts can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

The table below shows the Low frequency interrupt events.

Table 57-74. Low Frequency Interrupt Events

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

57.4.6.7.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

The following table shows the error interrupt events.

Table 57-75. Error Interrupt Events

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

57.5 USB Non-Core Memory Map/Register Definition

There are two kinds of registers in the USB module: USB core registers and USB non-core registers.

USB core registers are used to control USB core functions, and more independent of USB features. Each USB controller core has its own core registers.

USB non-core registers are additional to USB core registers, and more dependent on USB features. i.MX series products vary in non-core registers.

This section describes only the USB non-core registers. For detailed descriptions of USB core registers, please refer to [Register Interface](#).

NOTE

- For reserved bits, please preserve the value when writing (read its reset value, then write this value back)
- "USB_UOG1_", "USB_UOG2_" prefix in register name indicates it is a core register for OTG1/OTG2 controller core respectively.
- USBNC_USB_" prefix in register name indicates it is a USB non-core register.

USBNC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
218_4800	USB OTG1 Control Register (USBNC_USB_OTG1_CTRL)	32	R/W	3000_1000h	57.5.1/3602

USB_nHWTXBUF field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 TXCHANADD	TX FIFO Buffer size is: (2 ^{TXCHANADD}) * 4 Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. For the OTG controller operating in device mode, this is the FIFO buffer size per endpoint. As the OTG controller has 8 TX endpoint, there are 8 of these buffers.

Table continues on the next page...

USB_nHWTXBUF field descriptions (continued)

Field	Description
	For the OTG controller operating in host mode, or for Host-only controller, the entire buffer memory is used as a single TX buffer. Therefore, there is only 1 of this buffer
15–8 -	This field is reserved. Reserved
TXBURST	Default burst size for memory to TX buffer transfer. This is reset value of TXPBURST bits in USB core register USB_n_BURSTSIZE. Please see Programmable Burst Size (USB_nBURSTSIZE) .

57.6.6 RX Buffer Hardware Parameters (USB_nHWRXBUF)

Address: 218_4000h base + 14h offset + (512d × i), where i=0d to 1d

USB_nHWRXBUF field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 RXADD	Buffer total size for all receive endpoints is (2^RXADD). RX Buffer size is: (2^RXADD) * 4 Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. There is a single Receive FIFO buffer in the USB controller. The buffer is shared for all endpoints for the OTG controller in device mode.
RXBURST	Default burst size for memory to RX buffer transfer. This is reset value of RXPBURST bits in USB core register USB_n_BURSTSIZE. Please see Programmable Burst Size (USB_nBURSTSIZE) .

57.6.7 General Purpose Timer #0 Load (USB_nGPTIMER0LD)

This register controls load value of the count timer in register n_GPTIMER0CTRL. Please see [General Purpose Timer #0 Controller \(USB_nGPTIMER0CTRL\)](#) .

Address: 218_4000h base + 80h offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								GPTLD																							
W	0								0																							
Reset	0								0																							

USB_nGPTIMER0LD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
GPTLD	General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. NOTE: Max value is 0xFFFFF or 16.777215 seconds.

57.6.8 General Purpose Timer #0 Controller (USB_nGPTIMER0CTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI0 bit in n_USBSTS register (See [USB Status Register \(USB_nUSBSTS\)](#)), interrupt enable bit is TIE0 bit in n_USBINTR register. (See [Interrupt Enable Register \(USB_nUSBINTR\)](#) .)

57.6.12 Capability Registers Length (USB_nCAPLENGTH)

The Capability Registers Length register contains the address offset to the Operational registers relative to the CAPLENGTH register.

Address: 218_4000h base + 100h offset + (512d × i), where i=0d to 1d

Bit	7	6	5	4	3	2	1	0
Read	CAPLENGTH							
Write								
Reset	0	1	0	0	0	0	0	0

USB_nCAPLENGTH field descriptions

Field	Description
CAPLENGTH	These bits are used as an offset to add to register base to find the beginning of the Operational Register. Default value is '40h'.

57.6.13 Host Controller Interface Version (USB_nHCIVERSION)

This is a 2-byte register containing a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision.

Address: 218_4000h base + 102h offset + (512d × i), where i=0d to 1d

USB_nHCIVERSION field descriptions

Field	Description
HCIVERSION	Host Controller Interface Version Number Default value is '10h', which means EHCI rev1.0.

57.6.14 Host Controller Structural Parameters (USB_nHCSPARAMS)

The following figure shows the port steering logic capabilities of Host Control Structural Parameters (n_HCSPARAMS).

Address: 218_4000h base + 104h offset + (512d × i), where i=0d to 1d

USB_nHCSPARAMS field descriptions

Field	Description
31–28 -	This field is reserved. Reserved
27–24 N_TT	Number of Transaction Translators (N_TT). Default value '0000b' This field indicates the number of embedded transaction translators associated with the USB2.0 host controller. These bits would be set to '0001b' for Multi-Port Host, and '0000b' for Single-Port Host.
23–20 N_PTT	Number of Ports per Transaction Translator (N_PTT). Default value '0000b' This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. These bits would be set to equal N_PORTS for Multi-Port Host, and '0000b' for Single-Port Host.
19–17 -	This field is reserved. Reserved
16 PI	Port Indicators (P INDICATOR) This bit indicates whether the ports support port indicator control. When set to one, the port status and control registers include a read/writeable field for controlling the state of the port indicator This bit is "1b" in all controller core.
15–12 N_CC	Number of Companion Controller (N_CC). This field indicates the number of companion controllers associated with this USB2.0 host controller. These bits are '0000b' in all controller core. 0 There is no internal Companion Controller and port-ownership hand-off is not supported. 1 There are internal companion controller(s) and port-ownership hand-offs is supported.
11–8 N_PCC	Number of Ports per Companion Controller This field indicates the number of ports supported per internal Companion Controller. It is used to indicate the port routing configuration to the system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC. These bits are '0000b' in all controller core.
7–5 -	This field is reserved. Reserved
4 PPC	Port Power Control This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register
N_PORTS	Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register. Valid values are in the range of 1h to Fh. A zero in this field is undefined. These bits are always set to '0001b' because all controller cores are Single-Port Host.

57.6.15 Host Controller Capability Parameters (USB_nHCCPARAMS)

This register identifies multiple mode control (time-base bit functionality), addressing capability.

Address: 218_4000h base + 108h offset + (512d × i), where i=0d to 1d

USB_nHCCPARAMS field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 EECP	EHCI Extended Capabilities Pointer. This field indicates the existence of a capabilities list. A value of 00h indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. The pointer value must be 40h or greater if implemented to maintain the consistency of the PCI header defined for this class of device. NOTE: These bits are set '00h' in all controller core.
7–4 IST	Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. These bits are set '00h' in all controller core.
3 -	This field is reserved. Reserved

Table continues on the next page...

USB_nHCCPARAMS field descriptions (continued)

Field	Description
2 ASP	<p>Asynchronous Schedule Park Capability</p> <p>If this bit is set to a one, then the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the <i>Asynchronous Schedule Park Mode Enable</i> and <i>Asynchronous Schedule Park Mode Count</i> fields in the USBCMD register.</p> <p>NOTE: ASP bit reset value: '00b' for OTG controller core, '11b' for Host-only controller core.</p>
1 PFL	<p>Programmable Frame List Flag</p> <p>If this bit is set to zero, then the system software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero.</p> <p>If set to a one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous.</p> <p>This bit is set '1b' in all controller core.</p>
0 ADC	<p>64-bit Addressing Capability</p> <p>This bit is set '0b' in all controller core, no 64-bit addressing capability is supported.</p>

57.6.16 Device Controller Interface Version (USB_nDCIVERSION)

This register indicates the two-byte BCD encoding of the device controller interface version number.

Address: 218_4000h base + 120h offset + (512d × i), where i=0d to 1d

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31–9 -	This field is reserved. Reserved
8 HC	Host Capable When this bit is 1, this controller is capable of operating as an EHCI compatible USB 2.0 host controller.
7 DC	Device Capable When this bit is 1, this controller is capable of operating as a USB 2.0 device.
6–5 -	This field is reserved. Reserved
DEN	Device Endpoint Number This field indicates the number of endpoints built into the device controller. If this controller is not device capable, then this field will be zero. Valid values are 0 - 15.

57.6.18 USB Command Register (USB_nUSBCMD)

The Command Register indicates the command to be executed by the serial bus host/device controller. Writing to the register causes a command to be executed.

Address: 218_4000h base + 140h offset + (512d × i), where i=0d to 1d

USB_nUSBCMD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 ITC	Interrupt Threshold Control -Read/Write. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 0x00 Immediate (no threshold) 0x01 1 micro-frame 0x02 2 micro-frames 0x04 4 micro-frames 0x08 8 micro-frames 0x10 16 micro-frames

Table continues on the next page...

USB_nUSBCMD field descriptions (continued)

Field	Description
	0x20 32 micro-frames 0x40 64 micro-frames
15 FS_2	See also bits 3-2 Frame List Size - (Read/Write or Read Only). [host mode only] This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. NOTE: This field is made up from USBCMD bits 15, 3 and 2. Value Meaning 000 1024 elements (4096 bytes) Default value 001 512 elements (2048 bytes) 010 256 elements (1024 bytes) 011 128 elements (512 bytes) 100 64 elements (256 bytes) 101 32 elements (128 bytes) 110 16 elements (64 bytes) 111 8 elements (32 bytes)
14 -	This field is reserved. Reserved
13 SUTW	Setup TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (SLOM bit in USB core register n_USBMODE, see USB Device Mode (USB_nUSBMODE)) then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software. This bit would also be cleared by hardware when a hazard detected.
12 ATDTW	Add dTD TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software. This bit would also be cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.
11 ASPE	Asynchronous Schedule Park Mode Enable - Read/Write. If the <i>Asynchronous Park Capability</i> bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. NOTE: ASPE bit reset value: '0b' for OTG controller .
10 -	This field is reserved. Reserved
9–8 ASP	Asynchronous Schedule Park Mode Count - Read/Write. If the <i>Asynchronous Park Capability</i> bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is Read-Only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the

Table continues on the next page...

USB_nUSBCMD field descriptions (continued)

Field	Description
	Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when <i>Park Mode Enable</i> is a one as this will result in undefined behavior. This field is set to 3h in all controller core.
7 -	This field is reserved. Reserved
6 IAA	Interrupt on Async Advance Doorbell - Read/Write. This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results.
5 ASE	Asynchronous Schedule Enable - Read/Write. Default 0b. This bit controls whether the host controller skips processing the Asynchronous Schedule. Only the host controller uses this bit. Values Meaning 0 Do not process the Asynchronous Schedule. 1 Use the ASYNCLISTADDR register to access the Asynchronous Schedule.
4 PSE	Periodic Schedule Enable- Read/Write. Default 0b. This bit controls whether the host controller skips processing the Periodic Schedule. Only the host controller uses this bit. Values Meaning 0 Do not process the Periodic Schedule 1 Use the PERIODICLISTBASE register to access the Periodic Schedule.
3-2 FS_1	See description at bit 15
1 RST	Controller Reset (RESET) - Read/Write. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host operation mode: When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. Device operation mode:

Table continues on the next page...

USB_nUSBCMD field descriptions (continued)

Field	Description
	When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, because the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.
0 RS	<p>Run/Stop (RS) - Read/Write. Default 0b. 1=Run. 0=Stop.</p> <p>Host operation mode:</p> <p>When set to '1b', the Controller proceeds with the execution of the schedule. The Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the controller is in the Halted state (that is, HCHalted in the USBSTS register is a one).</p> <p>Device operation mode:</p> <p>Writing a one to this bit will cause the controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the controller has been properly initialized. Writing a 0 to this will cause a detach event.</p>

57.6.19 USB Status Register (USB_nUSBSTS)

This register indicates various states of the Host/Device Controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

Address: 218_4000h base + 144h offset + (512d × i), where i=0d to 1d

25 TI1	General Purpose Timer Interrupt 1(GPTINT1)--R/WC. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero, writing a one to this bit will clear it.
24 TI0	General Purpose Timer Interrupt 0(GPTINT0)--R/WC. This bit is set when the counter in the GPTIMER0CTRL register transitions to zero, writing a one to this bit clears it.
23–17 -	This field is reserved. Reserved
16 NAKI	NAK Interrupt Bit--RO. This bit is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all Enabled TX/RX Endpoint NAK bits are cleared.
15 AS	Asynchronous Schedule Status - Read Only. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
14 PS	Periodic Schedule Status - Read Only.

Table continues on the next page...

USB_nUSBSTS field descriptions (continued)

Field	Description
	<p>This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0).</p> <p>Only used in the host operation mode.</p>
13 RCL	<p>Reclamation - Read Only.</p> <p>This is a read-only status bit used to detect an empty asynchronous schedule.</p> <p>Only used in the host operation mode.</p>
12 HCH	<p>HCHalted - Read Only.</p> <p>This bit is a zero whenever the Run/Stop bit is a one. The Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Controller hardware (for example, an internal error).</p> <p>Only used in the host operation mode.</p> <p>Default value is '0b' for OTG core.</p> <p>This is because OTG core is not operating as host in default. Please see CM bit in USB_n_USBMODE register.</p> <p>NOTE: HCH bit reset value: '0b' for OTG controller core.</p>
11 -	<p>This field is reserved.</p> <p>Reserved</p>
10 ULPII	<p>ULPI Interrupt - R/WC.</p> <p>This bit will be set '1b' by hardware when there is an event completion in ULPI viewport.</p> <p>This bit is usable only if the controller support UPLI interface mode.</p>
9 -	<p>This field is reserved.</p> <p>Reserved</p>
8 SLI	<p>DCSuspend - R/WC.</p> <p>When a controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state.</p> <p>Only used in device operation mode.</p>
7 SRI	<p>SOF Received - R/WC.</p> <p>When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125ms in HS mode and will be synchronized to the actual SOF that is received.</p> <p>Because the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp.</p> <p>In host mode, this bit will be set every 125us and can be used by host controller driver as a time base.</p> <p>Software writes a 1 to this bit to clear it.</p>
6 URI	<p>USB Reset Received - R/WC.</p> <p>When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit.</p> <p>Only used in device operation mode.</p>

Table continues on the next page...

USB_nUSBSTS field descriptions (continued)

Field	Description
5 AAI	<p>Interrupt on Async Advance - R/WC.</p> <p>System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the n_USBCMD register. This status bit indicates the assertion of that interrupt source.</p> <p>Only used in host operation mode.</p>
4 SEI	<p>System Error- R/WC.</p> <p>This bit is will be set to '1b' when an Error response is seen to a read on the system interface.</p>
3 FRI	<p>Frame List Rollover - R/WC.</p> <p>The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USB_n_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles.</p> <p>Only used in host operation mode.</p>
2 PCI	<p>Port Change Detect - R/WC.</p> <p>The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port.</p> <p>The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively.</p>
1 UEI	<p>USB Error Interrupt (USBERRINT) - R/WC.</p> <p>When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set.</p> <p>The device controller detects resume signaling only.</p>
0 UI	<p>USB Interrupt (USBINT) - R/WC.</p> <p>This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set.</p> <p>This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.</p>

57.6.20 Interrupt Enable Register (USB_nUSBINTR)

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt source is active. The USB Status register (n_USBSTS) still shows interrupt sources even if they are disabled by the n_USBINTR register, allowing polling of interrupt events by the software.

Field	Description
	When this bit is one, and the UPI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
18 UAIE	USB Host Asynchronous Interrupt Enable When this bit is one, and the UAI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
17 -	This field is reserved. Reserved
16 NAKE	NAK Interrupt Enable When this bit is one and the NAKI bit in n_USBSTS register is a one the controller will issue an interrupt.
15–11 -	These bits are reserved and should be set to zero.
10 ULPIE	ULPI Interrupt Enable When this bit is one and the UPLI bit in n_USBSTS register is a one the controller will issue an interrupt. This bit is usable only if the controller support UPLI interface mode.
9 -	This field is reserved. Reserved
8 SLE	Sleep Interrupt Enable When this bit is one and the SLI bit in n_n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
7 SRE	SOF Received Interrupt Enable When this bit is one and the SRI bit in n_USBSTS register is a one the controller will issue an interrupt.
6 URE	USB Reset Interrupt Enable When this bit is one and the URI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
5 AAE	Async Advance Interrupt Enable When this bit is one and the AAI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
4 SEE	System Error Interrupt Enable When this bit is one and the SEI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
3 FRE	Frame List Rollover Interrupt Enable When this bit is one and the FRI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
2 PCE	Port Change Detect Interrupt Enable When this bit is one and the PCI bit in n_USBSTS register is a one the controller will issue an interrupt.
1 UEE	USB Error Interrupt Enable When this bit is one and the UEI bit in n_USBSTS register is a one the controller will issue an interrupt.
0 UE	USB Interrupt Enable When this bit is one and the UI bit in n_USBSTS register is a one the controller will issue an interrupt.

57.6.21 USB Frame Index (USB_nFRINDEX)

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the n_USBCMD register.

This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop hit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (that is, SOF for 125 us micro-frame.).

Address: 218_4000h base + 14Ch offset + (512d × i), where i=0d to 1d

USB_nFRINDEX field descriptions

Field	Description

57.6.22 Frame List Base Address (USB_nPERIODICLISTBASE)

Host Controller only

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (USB_n_FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

Address: 218_4000h base + 154h offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USB_nPERIODICLISTBASE field descriptions

Field	Description
31–12 BASEADR	Base Address (Low). These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.
-	This field is reserved. Reserved

57.6.23 Device Address (USB_nDEVICEADDR)

Device Controller only

The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS descriptor.

USB Core Memory Map/Register Definition

Address: 218_4000h base + 154h offset + (512d × i), where i=0d to 1d

USB_nDEVICEADDR field descriptions

Field	Description
31–25 USBADR	Device Address. These bits correspond to the USB device address
24 USBADRA	Device Address Advance. Default=0. When this bit is '0', any writes to USBADR are instantaneous. When this bit is written to a '1' at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). NOTE: After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
-	This field is reserved. Reserved

57.6.24 Next Asynch. Address (USB_nASYNCLISTADDR)

Host Controller only

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits [4:0] of this register cannot be modified by the system software and will always return a zero when read.

Address: 218_4000h base + 158h offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

16–8 TXPBURST	Programmable TX Burst Size. Default value is determined by TXBURST bits in n_HWTXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from system memory to the USB bus.
RXPBURST	Programmable RX Burst Size. Default value is determined by TXBURST bits in n_HWRXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory.

57.6.27 TX FIFO Fill Tuning (USB_nTXFILLTUNING)

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_{ff} = Time to fetch packet into TX FIFO up to specified level.

T_s = Total Packet Flight Time (send-only) packet

$T_s = T_0 + T_1$

T_p = Total Packet Time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure T_p remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is $< T_s$ then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a

mark will be made the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the `n_TSCHEALTH` (T_{ff}) described below.

NOTE

The reset value could vary from instance to instance. Please see the detail in bit field description and ignore reset value in summary table in this case!

Address: `218_4000h` base + `164h` offset + (`512d` × `i`), where `i=0d` to `1d`

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USB_nTXFILLTUNING field descriptions

Field	Description
31–22 -	This field is reserved. Reserved
21–16 TXFIFOTHRES	FIFO Burst Threshold. (Read/Write) This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in <code>USB_n_USBMODE</code> register is set. Default value is '0Ah' for OTG controller core.
15–13 -	This field is reserved. Reserved
12–8 TXSCHHEALTH	Scheduler Health Counter. (Read/Write To Clear) This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by <code>TXFIFOTHRES</code> before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper <code>TXSCHOH</code> . Writing to this register will clear the counter and this counter will max. at 31. Default value is '00h' for OTG controller core.
TXSCHOH	Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as T_{ff} . As an approximation, the value chosen for this register should limit the number of back-off events captured in the <code>TXSCHHEALTH</code> to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode. Default value is '08h' for OTG controller core.

57.6.28 Endpoint NAK (USB_nENDPTNAK)

Address: 218_4000h base + 178h offset + (512d × i), where i=0d to 1d

0 CF	Configure Flag Host software sets this bit as the last action in its process of configuring the Host Controller. This bit controls the default port-routing control logic. 0 Port routing control logic default-routes each port to an implementation dependent classic host controller. 1 Port routing control logic default-routes all ports to this host controller.

57.6.31 Port Status & Control (USB_nPORTSC1)

Host Controller

A host controller could implement one to eight port status and control registers. The number is determined by N_PORTs bits in HWSPARAMs register (please see [Host Controller Structural Parameters \(USB_nHCSPARAMS\)](#)). Software could read this parameter register to determine how many ports need service.

All controller cores on this product are Single-Port, so there is only one port status and control register for each controller core.

This register is only reset by power on reset or controller core reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port supports power control, this state remains until port power is supplied (by software).

Device Controller

A controller operating in device mode has only port register one (PORTSC1) and it does not support power control in that mode. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

Address: 218_4000h base + 184h offset + (512d × i), where i=0d to 1d

USB_nPORTSC1 field descriptions

Field	Description
31–30 PTS_1	NOTE: All USB port interface modes are listed in this field description, but not all are supported. For detail feature of each controller core, please see Features . The behaviour is unknown when unsupported interface mode is selected.
29 STS	Serial Transceiver Select 1 Serial Interface Engine is selected 0 Parallel Interface signals is selected Serial Interface Engine can be used in combination with UTMI+/ULPI physical interface to provide FS/LS signaling instead of the parallel interface signals. When this bit is set '1b', serial interface engine will be used instead of parallel interface signals. This bit has no effect unless PTS bits is set to select UTMI+/ULPI interface. The Serial/USB1.1 PHY/IC-USB will use the serial interface engine for FS/LS signaling regardless of this bit value.
28 PTW	Parallel Transceiver Width This bit has no effect if serial interface engine is used. For OTG1/OTG2 core, it is Read-Only. Reset value is '1b'. 0 Select the 8-bit UTMI interface [60MHz] 1 Select the 16-bit UTMI interface [30MHz]
27–26 PSPD	Port Speed - Read Only. This register field indicates the speed at which the port is operating. 00 Full Speed 01 Low Speed 10 High Speed 11 Undefined
25 PTS_2	See description at bits 31-30
24 PFSC	Port Force Full Speed Connect - Read/Write. Default = 0b. When this bit is set to '1b', the port will be forced to only connect at Full Speed, It disables the chirp sequence that allows the port to identify itself as High Speed. 1 Forced to full speed 0 Normal operation
23 PHCD	PHY Low Power Suspend - Clock Disable (PLPSCD) - Read/Write. Default = 0b. When this bit is set to '1b', the PHY clock is disabled. Reading this bit will indicate the status of the PHY clock. NOTE: The PHY clock cannot be disabled if it is being used as the system clock. In device mode, The PHY can be put into Low Power Suspend when the device is not running (USBCMD Run/Stop=0b) or the host has signalled suspend (PORTSC1 SUSPEND=1b). PHY Low power suspend will be cleared automatically when the host initials resume. Before forcing a resume from the device, the device controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software.

Table continues on the next page...

USB_nPORTSC1 field descriptions (continued)

Field	Description
	1 Disable PHY clock 0 Enable PHY clock
22 WKOC	Wake on Over-current Enable (WKOC_E) - Read/Write. Default = 0b. Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if <i>Port Power</i> (Port Status & Control (USB_nPORTSC1)) is zero.
21 WKDC	Wake on Disconnect Enable (WKDCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if <i>Port Power</i> (Port Status & Control (USB_nPORTSC1)) is zero or in device mode.
20 WKCEN	Wake on Connect Enable (WKCENNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if <i>Port Power</i> (Port Status & Control (USB_nPORTSC1)) is zero or in device mode.
19–16 PTC	Port Test Control - Read/Write. Default = 0000b. Refer to Port Test Mode for the operational model for using these test modes and the USB Specification Revision 2.0, Chapter 7 for details on each test mode. The FORCE_ENABLE_FS and FORCE_ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point. NOTE: <i>Low speed operations are not supported as a peripheral device.</i> Any other value than zero indicates that the port is operating in test mode. Value Specific Test 0000 TEST_MODE_DISABLE 0001 J_STATE 0010 K_STATE 0011 SE0 (host) / NAK (device) 0100 Packet 0101 FORCE_ENABLE_HS 0110 FORCE_ENABLE_FS 0111 FORCE_ENABLE_LS 1000-1111 Reserved
15–14 PIC	Port Indicator Control - Read/Write. Default = 0b. Writing to this field has no effect if the P_INDICATOR bit in the HCSPARAMS register is a zero. Refer to the USB Specification Revision 2.0 for a description on how these bits are to be used. This field is zero if <i>Port Power</i> is zero. Bit Value Meaning 00 Port indicators are off 01 Amber 10 Green 11 Undefined
13 PO	Port Owner-Read/Write. Default = 0.

Table continues on the next page...

USB_nPORTSC1 field descriptions (continued)

Field	Description
	<p>This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero. System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port.</p> <p>Port owner handoff is not supported in all controller cores, therefore this bit will always be 0.</p>
12 PP	<p>Port Power (PP)-Read/Write or Read Only.</p> <p>The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows:</p> <p>PPC</p> <p>PP Operation</p> <p>0</p> <p>1b <i>Read Only</i> - Host controller does not have port power control switches. Each port is hard-wired to power.</p> <p>1</p> <p>1b/0b - <i>Read/Write</i>. OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, etc.</p> <p>When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port).</p> <p>This feature is implemented in all controller cores (PPC = 1).</p>
11–10 LS	<p>Line Status-Read Only. These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines.</p> <p>In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS.</p> <p>In device mode, the use of linestate by the device controller driver is not necessary.</p> <p>The encoding of the bits are:</p> <p>Bits [11:10] Meaning</p> <p>00 SE0</p> <p>10 J-state</p> <p>01 K-state</p> <p>11 Undefined</p>
9 HSP	<p>High-Speed Port - Read Only. Default = 0b.</p> <p>When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode.</p> <p>NOTE: HSP is redundant with PSPD(bit 27, 26) but remained for compatibility.</p>
8 PR	<p>Port Reset - Read/Write or Read Only. Default = 0b.</p> <p>In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. Default 0.</p> <p>When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. <i>This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.</i></p>

Table continues on the next page...

USB_nPORTSC1 field descriptions (continued)

Field	Description
	<p>In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register.</p> <p>This field is zero if <i>Port Power</i>(Port Status & Control (USB_nPORTSC1)) is zero.</p>
<p>7 SUSP</p>	<p>Suspend - Read/Write or Read Only. Default = 0b.</p> <p>1=Port in suspend state. 0=Port not in suspend state.</p> <p>In Host Mode: Read/Write.</p> <p>Port Enabled Bit and Suspend bit of this register define the port states as follows:</p> <p>Bits [Port Enabled, Suspend] Port State</p> <p>0x Disable</p> <p>10 Enable</p> <p>11 Suspend</p> <p>When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB.</p> <p>The host controller will unconditionally set this bit to zero when software sets the <i>Force Port Resume</i> bit to zero. The host controller ignores a write of zero to this bit.</p> <p>If host software sets this bit to a one when the port is not enabled (that is, <i>Port enabled</i> bit is a zero) the results are undefined.</p> <p>This field is zero if <i>Port Power</i>(Port Status & Control (USB_nPORTSC1)) is zero in host mode.</p> <p>In Device Mode: Read Only.</p> <p>In device mode this bit is a read only status bit.</p>
<p>6 FPR</p>	<p>Force Port Resume -Read/Write. 1= Resume detected/driven on port. 0=No resume (K-state) detected/ driven on port. Default = 0.</p> <p>In Host Mode:</p> <p>Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the <i>Port Change Detect</i> bit in the USBSTS register is also set to one. <i>This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.</i></p> <p>Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation, clear the bit the port control state switches to HS or FS idle.</p> <p>This field is zero if <i>Port Power</i>(Port Status & Control (USB_nPORTSC1)) is zero in host mode.</p> <p>This bit is not-EHCI compatible.</p> <p>In Device mode:</p>

Table continues on the next page...

USB_nPORTSC1 field descriptions (continued)

Field	Description
	After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit will be cleared because a K-to-J transition detected, the <i>Port Change Detect</i> bit in the USBSTS register is also set to one.
5 OCC	Over-current Change-R/WC. Default=0. This bit is set '1b' by hardware when there is a change to Over-current Active. Software can clear this bit by writing a one to this bit position.
4 OCA	Over-current Active-Read Only. Default 0. This bit will automatically transition from one to zero when the over current condition is removed. 1 This port currently has an over-current condition 0 This port does not have an over-current condition.
3 PEC	Port Enable/Disable Change-R/WC. 1=Port enabled/disabled status has changed. 0=No change. Default = 0. In Host Mode: For the root hub, this bit is set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if <i>Port Power</i> (Port Status & Control (USB_nPORTSC1)) is zero. In Device mode: The device port is always enabled, so this bit is always '0b'.
2 PE	Port Enabled/Disabled-Read/Write. 1=Enable. 0=Disable. Default 0. In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if <i>Port Power</i> (Port Status & Control (USB_nPORTSC1)) is zero in host mode. In Device Mode: The device port is always enabled, so this bit is always '1b'.
1 CSC	Connect Status Change-R/WC. 1 =Change in Current Connect Status. 0=No change. Default 0. In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it. This field is zero if <i>Port Power</i> (Port Status & Control (USB_nPORTSC1)) is zero in host mode. In Device Mode: This bit is undefined in device controller mode.

Table continues on the next page...

USB_nPORTSC1 field descriptions (continued)

Field	Description
0 CCS	<p>Current Connect Status-Read Only.</p> <p>In Host Mode:</p> <p>1=Device is present on port. 0=No device is present. Default = 0. This value reflects the current state of the port, and may not correspond directly to the event that caused the <i>Connect Status Change</i> bit (Bit 1) to be set.</p> <p>This field is zero if <i>Port Power</i>(Port Status & Control (USB_nPORTSC1)) is zero in host mode.</p> <p>In Device Mode:</p> <p>1=Attached. 0=Not Attached. Default=0. A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USB_CMD register. It does not state the device being disconnected or suspended.</p>

57.6.32 On-The-Go Status & control (USB_nOTGSC)

This register is available only in OTG controller core. It has four sections:

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms does not cause an update of the status input register, or cause an OTG interrupt.

See also [USB Device Mode \(USB_nUSBMODE\)](#) register.

Address: 218_4000h base + 1A4h offset + (512d × i), where i=0d to 1d

USB_nOTGSC field descriptions

Field	Description
31 -	This field is reserved. Reserved
30 DPIE	Data Pulse Interrupt Enable
29 EN_1MS	1 millisecond timer Interrupt Enable - Read/Write
28 BSEIE	B Session End Interrupt Enable - Read/Write. Setting this bit enables the B session end interrupt.
27 BSVIE	B Session Valid Interrupt Enable - Read/Write. Setting this bit enables the B session valid interrupt.
26 ASVIE	A Session Valid Interrupt Enable - Read/Write. Setting this bit enables the A session valid interrupt.
25 AVVIE	A VBus Valid Interrupt Enable - Read/Write. Setting this bit enables the A VBus valid interrupt.
24 IDIE	USB ID Interrupt Enable - Read/Write. Setting this bit enables the USB ID interrupt.
23 -	This field is reserved. Reserved
22 DPIS	Data Pulse Interrupt Status - Read/Write to Clear. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC1(0)[PP] = 0. Software must write a one to clear this bit.
21 STATUS_1MS	1 millisecond timer Interrupt Status - Read/Write to Clear. This bit is set once every millisecond. Software must write a one to clear this bit.
20 BSEIS	B Session End Interrupt Status - Read/Write to Clear. This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit.
19 BSVIS	B Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the B session valid threshold. Software must write a one to clear this bit.
18 ASVIS	A Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the A session valid threshold. Software must write a one to clear this bit.
17 AVVIS	A VBus Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the VBus valid threshold on an A device. Software must write a one to clear this bit.
16 IDIS	USB ID Interrupt Status - Read/Write. This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.

Table continues on the next page...

USB_nOTGSC field descriptions (continued)

Field	Description
15 -	This field is reserved. Reserved
14 DPS	Data Bus Pulsing Status - Read Only. A '1' indicates data bus pulsing is being detected on the port.
13 TOG_1MS	1 millisecond timer toggle - Read Only. This bit toggles once per millisecond.
12 BSE	B Session End - Read Only. Indicates VBus is below the B session end threshold.
11 BSV	B Session Valid - Read Only. Indicates VBus is above the B session valid threshold.
10 ASV	A Session Valid - Read Only. Indicates VBus is above the A session valid threshold.
9 AVV	A VBus Valid - Read Only. Indicates VBus is above the A VBus valid threshold.
8 ID	USB ID - Read Only. 0 = A device, 1 = B device
7-6 -	This field is reserved. Reserved
5 IDPU	ID Pullup - Read/Write This bit provide control over the ID pull-up resistor; 0 = off, 1 = on [default]. When this bit is 0, the ID input will not be sampled.
4 DP	Data Pulsing - Read/Write. Setting this bit causes the pullup on DP to be asserted for data pulsing during SRP.
3 OT	OTG Termination - Read/Write. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.
2 -	This field is reserved. Reserved
1 VC	VBUS Charge - Read/Write. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP.
0 VD	VBUS_Discharge - Read/Write. Setting this bit causes VBus to discharge through a resistor.

57.6.33 USB Device Mode (USB_nUSBMODE)

Address: 218_4000h base + 1A8h offset + (512d × i), where i=0d to 1d

USB_nUSBMODE field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15 -	This field is reserved. Reserved
14–5 -	This field is reserved. Reserved
4 SDIS	Stream Disable Mode. (0 - Inactive [default]; 1 - Active) Device Mode: Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received are responded to with a NYET handshake when stream disable is active. Host Mode: Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB. NOTE: Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TX FIFO Fill Tuning (USB_nTXFILLTUNING) and TXTTFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature.

Table continues on the next page...

USB_nUSBMODE field descriptions (continued)

Field	Description
	NOTE: The use of this feature substantially limits of the overall USB performance that can be achieved.
3 SLOM	Setup Lockout Mode. In device mode, this bit controls behavior of the setup lock mechanism. See Control Endpoint Operation Model . 0 Setup Lockouts On (default); 1 Setup Lockouts Off (DCD requires use of Setup Data Buffer Tripwire in USB Command Register (USB_nUSBCMD) .
2 ES	Endian Select - Read/Write. This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The bit fields in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word. Bit Meaning 0 Little Endian [Default] 1 Big Endian
CM	Controller Mode - R/WO. Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host & device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the <i>RESET</i> bit in the USBCMD register before reprogramming this register. For OTG controller core, reset value is '00b'. 00 Idle [Default for combination host/device] 01 Reserved 10 Device Controller [Default for device only controller] 11 Host Controller [Default for host only controller]

57.6.34 Endpoint Setup Status (USB_nENDPTSETUPSTAT)

Address: 218_4000h base + 1ACh offset + (512d × i), where i=0d to 1d

USB_nENDPTSETUPSTAT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
ENDPTSETUPSTAT	Setup Endpoint Status. For every setup transaction that is received, a corresponding bit in this register is set to one. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from Queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lock our mechanism is engaged. See Managing Endpoints in the Device Operational Model. This register is only used in device mode.

57.6.35 Endpoint Prime (USB_nENDPTPRIME)

This register is only used in device mode.

When software sets the prime bit for a given endpoint, the device controller loads the transfer descriptor, pointed to by the queue head, such that the endpoint is ready to transmit or receive when the host sends a request (IN/OUT token). The endpoint will NAK all requests from the host until the endpoint is primed. The controller will automatically re-prime the endpoint with a new transfer descriptor when one is found via the next_dtd pointer of the current transfer descriptor. Hence, the prime bit must only be set by software when a descriptor is added to the queue head.

Address: 218_4000h base + 1B0h offset + (512d × i), where i=0d to 1d

USB_nENDPTPRIME field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 PETB	Prime Endpoint Transmit Buffer - R/WS. For each endpoint a corresponding bit is used to request that a buffer is prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction. Software should write a one to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. NOTE: These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PETB[N] - Endpoint #N, N is in 0..7
15–8 -	This field is reserved. Reserved
PERB	Prime Endpoint Receive Buffer - R/WS. For each endpoint, a corresponding bit is used to request a buffer prepare for a receive operation for when a USB host initiates a USB OUT transaction. Software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. NOTE: These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PERB[N] - Endpoint #N, N is in 0..7

57.6.36 Endpoint Flush (USB_nENDPTFLUSH)

This register is only used in device mode.

Address: 218_4000h base + 1B4h offset + (512d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

23 TXE	TX Endpoint Enable 0 Disabled [Default] 1 Enabled An Endpoint should be enabled only after it has been configured.

Table continues on the next page...

USB_nENDPTCTRL2 field descriptions (continued)

Field	Description
22 TXR	TX Data Toggle Reset (WS) Write 1 - Reset PID Sequence Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the Host and device.
21 TXI	TX Data Toggle Inhibit 0 PID Sequencing Enabled. [Default] 1 PID Sequencing Disabled. This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet.
20 -	This field is reserved. Reserved
19–18 TXT	TX Endpoint Type - Read/Write 00 Control 01 Isochronous 10 Bulk 11 Interrupt
17 TXD	TX Endpoint Data Source - Read/Write 0 Dual Port Memory Buffer/DMA Engine [DEFAULT] Should always be written as 0.
16 TXS	TX Endpoint Stall - Read/Write 0 End Point OK 1 End Point Stalled This bit will be cleared automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint and this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints. NOTE: [CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit.
15–8 -	This field is reserved. Reserved
7 RXE	RX Endpoint Enable 0 Disabled [Default] 1 Enabled An Endpoint should be enabled only after it has been configured.
6 RXR	RX Data Toggle Reset (WS) Write 1 - Reset PID Sequence

Table continues on the next page...

USB_nENDPTCTRL2 field descriptions (continued)

Field	Description
	Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the host and device.
5 RXI	RX Data Toggle Inhibit 0 Disabled [Default] 1 Enabled This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always accept data packet regardless of their data PID.
4 -	This field is reserved. Reserved.
3-2 RXT	RX Endpoint Type - Read/Write 00 Control 01 Isochronous 10 Bulk 11 Interrupt
1 RXD	RX Endpoint Data Sink - Read/Write 0 Dual Port Memory Buffer/DMA Engine [Default] Should always be written as zero.
0 RXS	RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled This bit is set automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint and this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints. NOTE: [CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit.

57.6.42 Endpoint Control 3 (USB_nENDPTCTRL3)

This is endpoint control register for endpoint 3 in device operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control

causes undefined behavior for the data pid tracking on the active endpoint/direction.

Chapter 58

Universal Serial Bus 2.0 Integrated PHY (USB-PHY)

58.1 USB PHY Overview

The chip contains 2 integrated USB 2.0 PHY macrocells capable of connecting to USB host/device systems at the USB low-speed (LS) rate of 1.5 Mbits/s, full-speed (FS) rate of 12 Mbits/s or at the USB 2.0 high-speed (HS) rate of 480 Mbits/s.

The integrated PHY provides a standard UTM interface. The USB_*n*_DN and USB_*n*_DP pins connect directly to a USB connector.

The following subsections describe the external interfaces, internal interfaces, major blocks, and programmable registers that comprise the integrated USB 2.0 PHY.

58.2 Operation

The UTM provides a 16-bit interface to the USB controller. This interface is clocked at 30 MHz.

- The digital portions of the USBPHY block include the UTMI, digital transmitter, digital receiver, and the programmable registers.
- The analog transceiver section comprises an analog receiver and an analog transmitter, as shown in [Figure 58-1](#).

58.2.1 UTMI

The UTMI block handles the line_state bits, reset buffering, suspend distribution, transceiver speed selection, and transceiver termination selection.

The PLL supplies a 120 MHz signal to all of the digital logic. The UTMI block does a final divide-by-four to develop the 30 MHz clock used in the interface.

58.2.2 Digital Transmitter

The digital transmitter receives the 16-bit transmit data from the USB controller and handles the tx_valid, tx_validh and tx_ready handshake.

In addition, it contains the transmit serializer that converts the 16-bit parallel words at 30 MHz to a single bitstream at 480 Mbit for high-speed or 12 Mbit for full-speed or 1.5 Mbit for low-speed. It does this while implementing the bit-stuffing algorithm and the NRZI encoder that are used to remove the DC component from the serial bitstream. The output of this encoder is sent to the low-speed (LS), full-speed (FS) or high-speed (HS) drivers in the analog transceiver section's transmitter block.

58.2.3 Digital Receiver

The digital receiver receives the raw serial bitstream from the low speed (LS) differential transceiver, full speed (FS) differential transceiver, and a 9X, 480 MHz sampled data from the high speed (HS) differential transceiver.

As the phase of the USB host transmitter shifts relative to the local PLL, the receiver section's HS DLL tracks these changes to give a reliable sample of the incoming 480 Mbit/s bitstream. Since this sample point shifts relative to the PLL phase used by the digital logic, a rate-matching elastic buffer is provided to cross this clock domain boundary. Once the bitstream is in the local clock domain, an NRZI decoder and bit unstuffer restore the original payload data bitstream and pass it to a deserializer and holding register. The receive state machine handles the rx_valid, rx_validh, and handshake with the USB controller. The handshake is not interlocked, in that there is no rx_ready signal coming from the controller. The controller must take each 16-bit value as presented by the PHY. The receive state machine provides an rx_active signal to the controller that indicates when it is inside a valid packet (SYNC detected, and so on).

58.2.4 Analog Receiver

The analog receiver comprises five differential receivers, two single-ended receivers, and a 9X, 480 MHz HS data sampling module

, as shown in the figure below and described further in this section.

Figure 58-1. USB 2.0 PHY Analog Transceiver Block Diagram

58.2.4.1 HS Differential Receiver

The high-speed differential receiver is both a differential analog receiver and threshold comparator. Its output is a one if the differential signal is greater than a 0-V threshold.

Otherwise, its output is 0. Its purpose is to discriminate the ± 400 -mV differential voltage resulting from the high-speed drivers current flow into the dual 45Ω terminations found on each pin of the differential pair. The envelope or squelch detector, described below, ensures that the differential signal has sufficient magnitude to be valid. The HS differential receiver tolerates up to 500 mV of common mode offset.

58.2.4.2 Squelch Detector

The squelch detector is a differential analog receiver and threshold comparator.

Its output is 1, if the differential magnitude is less than a nominal 100 mV threshold. Otherwise, its output is 0.

Its purpose is to invalidate the HS differential receiver when the incoming signal is simply too low to receive reliably.

58.2.4.3 LS/FS Differential Receiver

The low-speed/full-speed differential receiver is both a differential analog receiver and threshold comparator.

The crossover voltage falls between 1.3 V and 2.0 V. Its output is 1, when the USB_n_DP line is above the crossover point and the USB_n_DN line is below the crossover point. The digital receiver section decodes the receiver data into J or K state according to the speed.

58.2.4.4 HS Disconnect Detector

It is a differential analog receiver and threshold comparator. It outputs high when differential magnitude is greater than a nominal 575-mV threshold. Otherwise, it outputs low.

58.2.4.5 USB Plugged-In Detector

The USB plugged-in detector looks for both USB_n_DP and USB_n_DN to be high. There is a pair of large on-chip pullup resistors (200 K Ω) that hold both USB_n_DP and USB_n_DN high when the USB cable is not attached. The USB plugged-in detector signals a 0 in this case.

When operating in device mode, the upstream port in host/hub interface contains a 15 K Ω pulldown resistor which could easily override the 200 K Ω pullup resistor. When plugged in, at least one signal in the pair will be low, which will force the plugged-in detector's output high.

58.2.4.6 Single-Ended USB_DP Receiver

The single-ended USB_n_DP receiver output is high whenever the USB_n_DP input is above its nominal 1.8 V threshold.

58.2.4.7 Single-Ended USB_DN Receiver

The single-ended USB_n_DN receiver output is high whenever the USB_n_DN input is above its nominal 1.8 V threshold.

58.2.4.8 9X Oversample Module

The 9X oversample module uses nine identically spaced phases of the 480 MHz clock to sample a high speed bit data. The squelch signal is sampled only 1X.

58.2.5 Analog Transmitter

The analog transmitter comprises two differential drivers: one for high-speed signaling and one for full-speed signaling. It also contains the switchable 1.5 K Ω pullup resistor.

See [Figure 58-1](#).

58.2.5.1 Switchable High-Speed 45 Ω Termination Resistors

High-speed current mode differential signaling requires good 90 Ω differential termination at each end of the USB cable. This results from switching in 45 Ω terminating resistors from each signal line to ground at each end of the cable.

Because each signal is parallel terminated with 45 Ω at each end, each driver sees a 22.5 Ω load. This load impedance is much too low for full-speed signaling levels—hence the need for switchable high-speed terminating resistors. Switchable trimming resistors are provided to tune the actual termination resistance of each device, as shown in [Figure](#)

58-2. The HW_USBPHY_TX_TXCAL45DP bit field, for example, allows one of 16 trimming resistor values to be placed in parallel with the 45 Ω terminator on the USB_n_DP signal.

58.2.5.2 Low-Speed/Full-Speed Differential Driver

The low-speed/full-speed differential drivers are essentially low-impedance pulldown devices that are switched in a differential mode for low-speed or full-speed signaling, that is, either one or the other device is turned on to signal the "J" state or the "K" state.

58.2.5.3 High-Speed Differential Driver

The high-speed differential driver receives a 17.78 mA current from the constant current source (I_{ref}) and essentially steers it down either the USB_DP signal or the USB_DN signal or alternatively to ground.

This current will produce approximately a 400 mV drop across the 22.5 Ω termination seen by the driver when it is steered onto one of the signal lines. The approximately 17.78 mA current source is referenced back to the integrated voltage-band-gap (V_{bg}) circuit. The I_{ref} , I_{bias} , and V to I circuits are shared with the integrated battery charger.

58.2.5.4 Switchable 1.5K Ω USB_DP Pullup Resistor

This product contains a switchable 1.5 K Ω pullup resistor on the USB_n_DP signal.

This resistor is switched on to indicate to the host/hub controller that a full-speed-capable device is on the USB cable, powered on, and ready. This resistor is switched off at power-on reset so the host does not recognize a USB device until the processor software enables the announcement of a full-speed device.

58.2.5.5 Switchable 15KΩ USB_DP Pulldown Resistor

This product contains a switchable 15 KΩ pulldown resistor on both USB_n_DP and USB_n_DN signals. This is used in host mode to indicate to the device controller that a host is present.

Figure 58-2. USB 2.0 PHY Transmitter Block Diagram

58.2.6 Recommended Register Configuration for USB Certification

The register settings in this section are recommended for passing USB certification.

The following settings lower the J/K levels to certifiable limits:

```
HW_USBPHY_TX_TXCAL45DP = 0x0
HW_USBPHY_TX_TXCAL45DN = 0x0
HW_USBPHY_TX_D_CAL = 0x7
```

58.2.7 Charger detection

The USB charger detector is a block that detects whether the upstream-facing device is connected to a down-stream facing charger, either a dedicated USB charger or a host charger.

The USB charger detector is comprised of two sub-blocks, namely the USB data-pin contact detector and the charger detector.

This section details those two sub-blocks and gives the software flow of USB charger detection. Finally, this chapter discusses the detection of a USB charger in case of a dead battery.

58.2.7.1 Charger detect control table

Before we dive into the details of the detectors, we show the logic table of the control signals to give the user an overall picture of the charger detector.

Table 58-1. Charger detection control table

EN_B	CHK_CHRG_B	CHK_CONTACT	Data pin contact detector	Charger detector
0	1	1	Enabled	Disabled
0	0	x(don't care)	Disabled	Enabled
1	x	x(don't care)	Disabled	Disabled

58.2.7.2 Data pin contact detector

According to Battery Charging Specification (rev 1.2), USB plugs and receptacles are designed such that when the plug is inserted into the receptacle, the power pins make contact before the data pins make contact. Therefore, there is inevitably a time interval during which USB_n_VBUS has been observed by the device while the USB_n_DP and USB_n_DN pins are not still pending for contact. The USB data pin contact detector is designed to give the software an indication of the contact of the data pins.

To enable the USB data pin contact detector, the user should set the CHK_CONTACT bit of the USB1_CHRG_DETECT register to 1 and monitor the PLUG_CONTACT bit status of the USB1_CHRG_DETECT_STAT register. If PLUG_CONTACT is 1, then it indicates that the data pins have made good contacts, otherwise the user should continue to wait until this bit is set.

According to Table 1, it should be noted that the data pin contact detector only works when EN_B=0 and CHK_CHRG_B=1, both bits being of the USB1_CHRG_DETECT register.

58.2.7.3 Charger detector

Once the data pins make contact, the user should enable the charger detector by clearing the CHK_CHRG_B bit that is low-active. Then the user should wait for 40ms and then check the status bit of CHRGM_DETECTED in register hw_anadig_usb1_chrg_det_stat. CHRGM_DETECTED=1 means that the device is connected to a charger, either a dedicated charger or a charging downstream port (or equivalently called a host charger, or charging host). To further differentiate between a host charger and a dedicated charger, the user is suggested to pull up USB_n_DP signaling a connect event to the host. Then the user should monitor the USB_n_DN line status. If USB_n_DN=1, then the charger is a dedicated charger; if USB_n_DN=0, then it is a host charger.

58.2.7.4 Charger detection software flow

Upon seeing VBUS, the software should follow the software flow for the charger detection process. The flow chart mentions the "enable the vdd3p0 current limiter". Please refer to the power chapter for details.

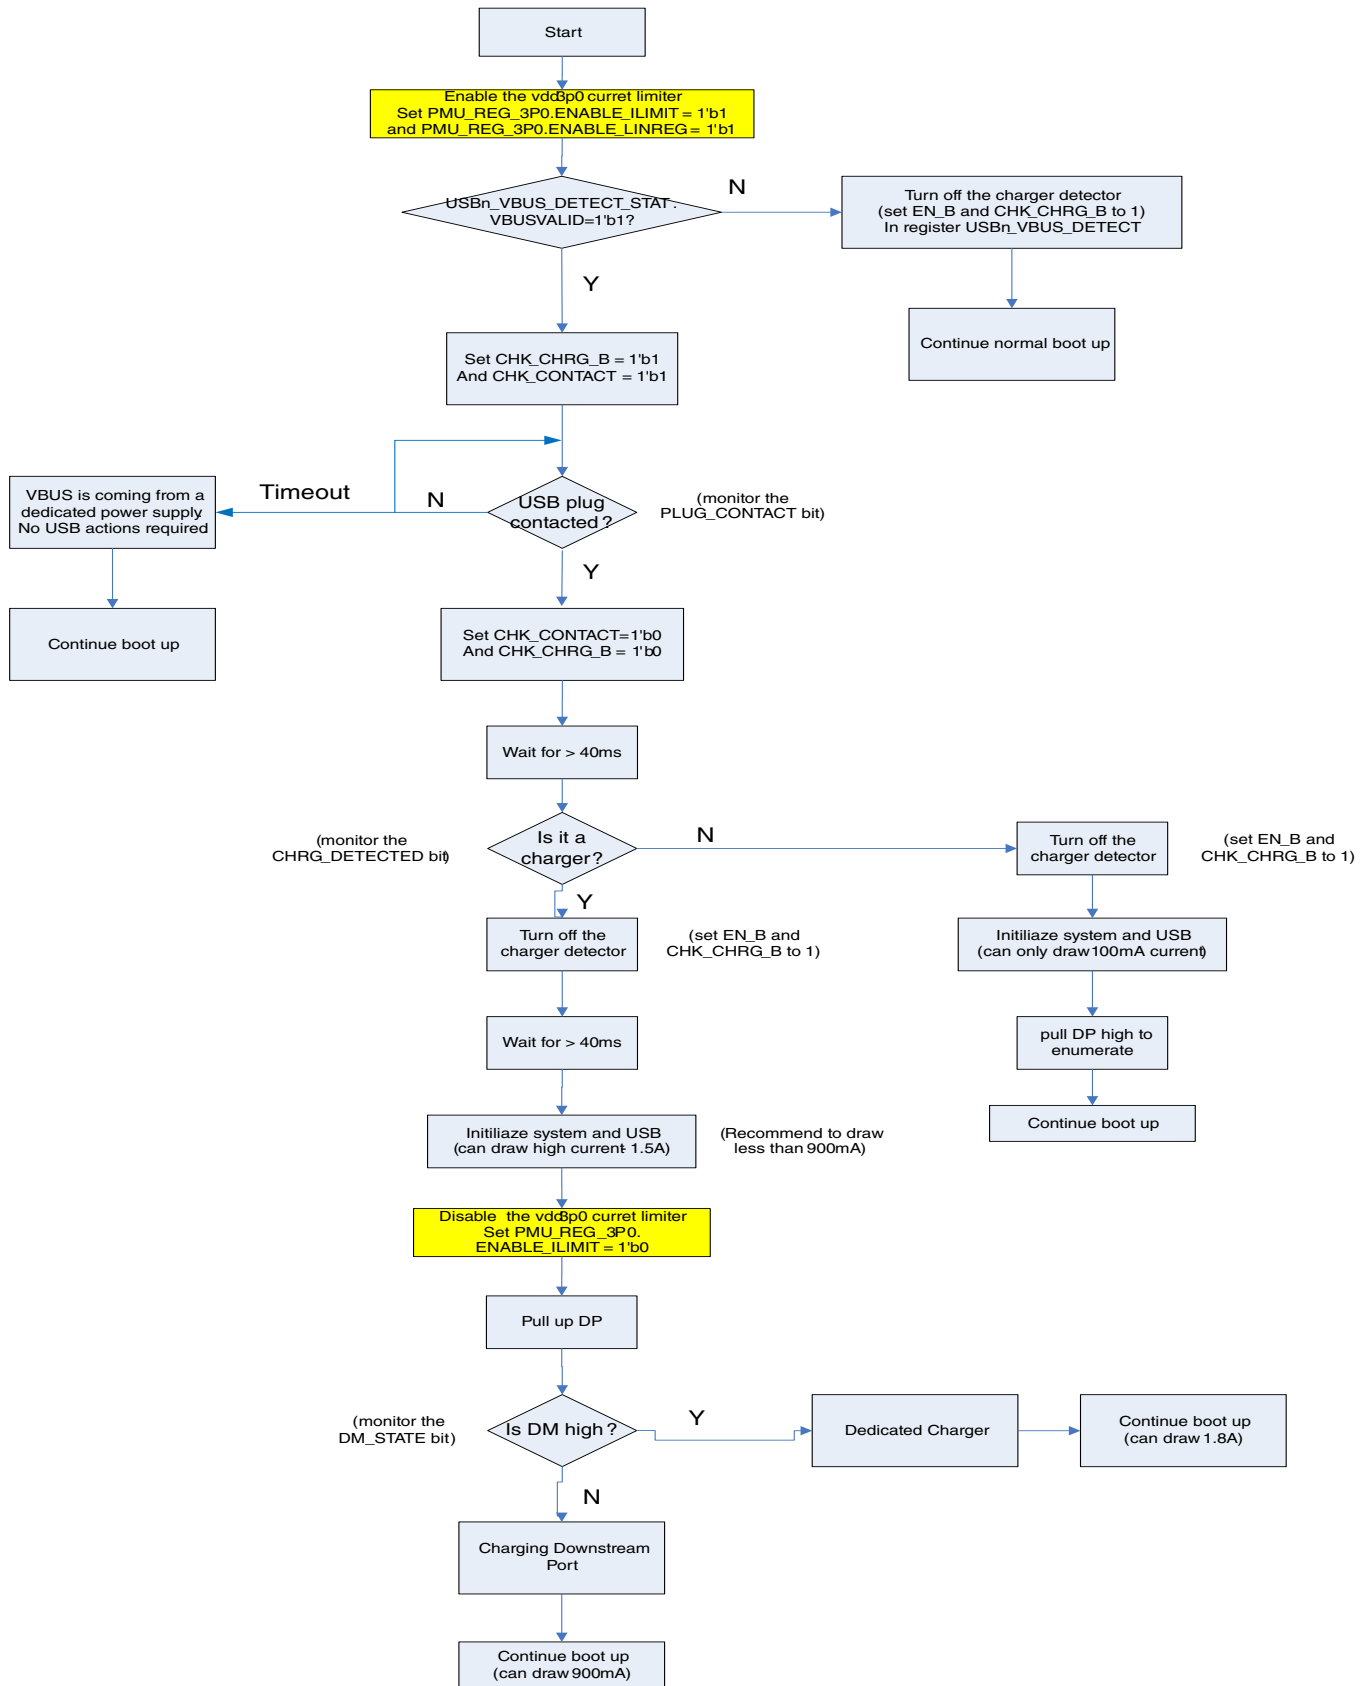

Figure 58-3. USBPHY Charger Detection Software Flow

58.2.7.5 Dead Battery Protect

All the descriptions above are based on the assumption that all the power supplies have been on when the device is plugged into a remote host (or charger). However, there are cases when the local battery of the portable device has been so depleted that the system could not be turned on. In such scenarios the user may prefer a method of signaling the external power management unit (PMIC) the existence of the USB charger to draw a current larger than 100mA from the remote host to speed up system boot up or battery charging. The charger detector indeed supports this function.

When we have a fully depleted battery, all the power supplies might be off. Upon insertion of the 5V, the supplies are brought up by the external PMIC and the internal regulators. Due to the 100mA inrush current limit of the USB spec, we cannot draw larger than 100mA current which might be a limit for system boot-up. Since by default, EN_B=0, CHK_CHRG_B=0 and CHK_CONTACT=1, the usb charger detector is automatically enabled without any software operation needed and it can signal the external PMIC the existence of a USB charger through the open-drain output pin USB_OTG_CHD_B. This pin should be pulled up to an external voltage that is acceptable to the PMIC. If this signal is low, then the PMIC can get that the device is connected to a charger. In this case, the PMIC can draw more than 100mA current from the USB.

It should be noted that this function requires cooperation between the chip and the external PMIC. It is suggested that the user consult Freescale for such use cases.

58.3 USB PHY Memory Map/Register Definition

USBPHY Hardware Register Format Summary

USBPHY memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
20C_9000	USB PHY Power-Down Register (USBPHY1_PWD)	32	R/W	001E_1C00h	58.3.1/3698

58.3.1 USB PHY Power-Down Register (USBPHYx_PWDn)

The USB PHY Power-Down Register provides overall control of the PHY power state. Before programming this register, the PHY clocks must be enabled in registers USBPHYx_CTRLn and CCM_ANALOG_USBPHYx_PLL_480_CTRLn.

Address: Base address + 0h offset + (4d × i), where i=0d to 3d

USBPHYx_PWDn field descriptions

Field	Description
31–21 RSVD2	Reserved.
20 RXPWDRX	0 = Normal operation. 1 = Power-down the entire USB PHY receiver block except for the full-speed differential receiver. Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.
19 RXPWDDIFF	0 = Normal operation. 1 = Power-down the USB high-speed differential receiver.

Table continues on the next page...

USBPHYx_PWDn field descriptions (continued)

Field	Description
	Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.
18 RXPWD1PT1	0 = Normal operation. 1 = Power-down the USB full-speed differential receiver. Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.
17 RXPWDENV	0 = Normal operation. 1 = Power-down the USB high-speed receiver envelope detector (squelch signal). Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.
16–13 RSVD1	Reserved.
12 TXPWDV2I	0 = Normal operation. 1 = Power-down the USB PHY transmit V-to-I converter and the current mirror. Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled. Note that these circuits are shared with the battery charge circuit. Setting this to 1 does not power-down these circuits, unless the corresponding bit in the battery charger is also set for power-down.
11 TXPWDIBIAS	0 = Normal operation. 1 = Power-down the USB PHY current bias block for the transmitter. This bit should be set only when the USB is in suspend mode. This effectively powers down the entire USB transmit path. Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled. Note that these circuits are shared with the battery charge circuit. Setting this bit to 1 does not power-down these circuits, unless the corresponding bit in the battery charger is also set for power-down.
10 TXPWDIFS	0 = Normal operation. 1 = Power-down the USB full-speed drivers. This turns off the current starvation sources and puts the drivers into high-impedance output. Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.
RSVD0	Reserved.

58.3.2 USB PHY Transmitter Control Register (USBPHYx_TXn)

The USB PHY Transmitter Control Register handles the transmit controls.

Address: Base address + 10h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD5			USBPHY_TX_EDGECTRL			RSVD2				TXCAL45DP					
W	[Greyed out]			[Greyed out]			[Greyed out]				[Greyed out]					
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	1	1	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	[Greyed out]				[Greyed out]				[Greyed out]				[Greyed out]			
Reset	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1	1

USBPHYx_TXn field descriptions

Field	Description
31–29 RSVD5	Reserved.
28–26 USBPHY_TX_EDGECTRL	Controls the edge-rate of the current sensing transistors used in HS transmit. NOT FOR CUSTOMER USE.
25–20 RSVD2	Reserved.
19–16 TXCAL45DP	Decode to select a 45-Ohm resistance to the USB_DP output pin. Maximum resistance = 0000. Resistance is centered by design at 0110.
15–12 RSVD1	Reserved. Note: This bit should remain clear.
11–8 TXCAL45DN	Decode to select a 45-Ohm resistance to the USB_DN output pin. Maximum resistance = 0000. Resistance is centered by design at 0110.
7–4 RSVD0	Reserved. Note: This bit should remain clear.
D_CAL	Resistor Trimming Code: 0000 = 0.16% 0111 = Nominal 1111 = +25%

58.3.3 USB PHY Receiver Control Register (USBPHYx_RXn)

The USB PHY Receiver Control Register handles receive path controls.

Address: Base address + 20h offset + (4d × i), where i=0d to 3d

USBPHYx_RXn field descriptions

Field	Description
31–23 RSVD2	Reserved.
22 RXDBYPASS	0 = Normal operation. 1 = Use the output of the USB_DP single-ended receiver in place of the full-speed differential receiver. This test mode is intended for lab use only.
21–7 RSVD1	Reserved.

Table continues on the next page...

USBPHYx_RXn field descriptions (continued)

Field	Description
6-4 DISCONADJ	The DISCONADJ field adjusts the trip point for the disconnect detector: 000 = Trip-Level Voltage is 0.57500 V 001 = Trip-Level Voltage is 0.56875 V 010 = Trip-Level Voltage is 0.58125 V 011 = Trip-Level Voltage is 0.58750 V 1XX = Reserved
3 RSVD0	Reserved.
ENVADJ	The ENVADJ field adjusts the trip point for the envelope detector. 000 = Trip-Level Voltage is 0.12500 V 001 = Trip-Level Voltage is 0.10000 V 010 = Trip-Level Voltage is 0.13750 V 011 = Trip-Level Voltage is 0.15000 V 1XX = Reserved

58.3.4 USB PHY General Control Register (USBPHYx_CTRLn)

The USB PHY General Control Register handles OTG and Host controls. This register also includes interrupt enables and connectivity detect enables and results.

Address: Base address + 30h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHYx_CTRLn field descriptions

Field	Description
31 SFTRST	Writing a 1 to this bit will soft-reset the USBPHYx_PWD, USBPHYx_TX, USBPHYx_RX, and USBPHYx_CTRL registers. Set to 0 to release the PHY from reset.
30 CLKGATE	Gate UTMI Clocks. Clear to 0 to run clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated. Note this bit can be auto-cleared if there is any wakeup event when USB is suspended while ENAUTOCLR_CLKGATE bit of USBPHYx_CTRL is enabled.
29 UTMI_SUSPENDM	Used by the PHY to indicate a powered-down state. If all the power-down bits in the USBPHYx_PWD are enabled, UTMI_SUSPENDM will be 0, otherwise 1. UTMI_SUSPENDM is negative logic, as required by the UTMI specification.
28 HOST_FORCE_LS_SE0	Forces the next FS packet that is transmitted to have a EOP with LS timing. This bit is used in host mode for the resume sequence. After the packet is transferred, this bit is cleared. The design can use this function to force the LS SE0 or use the USBPHYx_CTRL_UTMI_SUSPENDM to trigger this event when leaving suspend. This bit is used in conjunction with USBPHYx_DEBUG_HOST_RESUME_DEBUG.
27 OTG_ID_VALUE	Almost same as OTGID_STATUS in USBPHYx_STATUS Register. The only difference is that OTG_ID_VALUE has debounce logic to filter the glitches on ID Pad.
26–25 RSVD1	Reserved.
24 FSDLL_RST_EN	Enables the feature to reset the FSDLL lock detection logic at the end of each TX packet.
23 ENVBUSCHG_WKUP	Enables the feature to wakeup USB if VBUS is toggled when USB is suspended.
22 ENIDCHG_WKUP	Enables the feature to wakeup USB if ID is toggled when USB is suspended.
21 ENDPDMCHG_WKUP	Enables the feature to wakeup USB if DP/DM is toggled when USB is suspended. This bit is enabled by default.
20 ENAUTOCLR_PHY_PWD	Enables the feature to auto-clear the PWD register bits in USBPHYx_PWD if there is wakeup event while USB is suspended. This should be enabled if needs to support auto wakeup without S/W's interaction.
19 ENAUTOCLR_CLKGATE	Enables the feature to auto-clear the CLKGATE bit if there is wakeup event while USB is suspended. This should be enabled if needs to support auto wakeup without S/W's interaction.
18 RSVD0	Reserved.
17 WAKEUP_IRQ	Indicates that there is a wakeup event. Reset this bit by writing a 1 to the clear address space and not by a general write.
16 ENIRQWAKEUP	Enables interrupt for the wakeup events.
15 ENUTMILEVEL3	Enables UTMI+ Level3. This should be enabled if needs to support external FS Hub with LS device connected
14 ENUTMILEVEL2	Enables UTMI+ Level2. This should be enabled if needs to support LS device
13 DATA_ON_LRADC	Enables the LRADC to monitor USB_DP and USB_DM. This is for use in non-USB modes only.
12 DEVPLUGIN_IRQ	Indicates that the device is connected. Reset this bit by writing a 1 to the clear address space and not by a general write.
11 ENIRQDEVPLUGIN	Enables interrupt for the detection of connectivity to the USB line.

Table continues on the next page...

USBPHYx_CTRLn field descriptions (continued)

Field	Description
10 RESUME_IRQ	Indicates that the host is sending a wake-up after suspend. This bit is also set on a reset during suspend. Use this bit to wake up from suspend for either the resume or the reset case. Reset this bit by writing a 1 to the clear address space and not by a general write.
9 ENIRQRESUMEDTECT	Enables interrupt for detection of a non-J state on the USB line. This should only be enabled after the device has entered suspend mode.
8 RESUMEIRQSTICKY	Set to 1 will make RESUME_IRQ bit a sticky bit until software clear it. Set to 0, RESUME_IRQ only set during the wake-up period.
7 ENOTGIDDETECT	Enables circuit to detect resistance of MiniAB ID pin.
6 OTG_ID_CHG_IRQ	OTG ID change interrupt. Indicates the value of ID pin changed.
5 DEVPLUGIN_POLARITY	For device mode, if this bit is cleared to 0, then it trips the interrupt if the device is plugged in. If set to 1, then it trips the interrupt if the device is unplugged.
4 ENDEVPLUGINDETECT	For device mode, enables 200-KOhm pullups for detecting connectivity to the host.
3 HOSTDISCONDETECT_IRQ	Indicates that the device has disconnected in high-speed mode. Reset this bit by writing a 1 to the clear address space and not by a general write.
2 ENIRQHOSTDISCON	Enables interrupt for detection of disconnection to Device when in high-speed host mode. This should be enabled after ENDEVPLUGINDETECT is enabled.
1 ENHOSTDISCONDETECT	For host mode, enables high-speed disconnect detector. This signal allows the override of enabling the detection that is normally done in the UTMI controller. The UTMI controller enables this circuit whenever the host sends a start-of-frame packet. SW shall set this bit when it found the high-speed device is connected, suggested during bus reset, after found high-speed device in USB_PORTSC1.PSPD). SW shall make sure this bit is not set at the end of resume, otherwise a wrong disconnect status may be detected. Suggest clear it after set USB_PORTSC1.SUSP, set it again after resume is ended(USB_PORTSC1.FPR==0).
0 ENOTG_ID_CHG_IRQ	Enable OTG_ID_CHG_IRQ.

58.3.5 USB PHY Status Register (USBPHYx_STATUS)

The USB PHY Status Register holds results of IRQ and other detects.

Address: Base address + 40h offset

USBPHYx_STATUS field descriptions

Field	Description
31–11 RSVD4	Reserved.
10 RESUME_STATUS	Indicates that the host is sending a wake-up after suspend and has triggered an interrupt.
9 RSVD3	Reserved.
8 OTGID_STATUS	Indicates the results of ID pin on MiniAB plug. False (0) is when ID resistance is less than Ra_Plug_ID, indicating host (A) side. True (1) is when ID resistance is greater than Rb_Plug_ID, indicating device (B) side.
7 RSVD2	Reserved.
6 DEVPLUGIN_STATUS	Indicates that the device has been connected on the USB_DP and USB_DM lines.
5–4 RSVD1	Reserved.
3 HOSTDISCONDETECT_STATUS	Indicates that the device has disconnected while in high-speed host mode.
RSVD0	Reserved.

58.3.6 USB PHY Debug Register (USBPHYx_DEBUGn)

This register is used to debug the USB PHY.

Address: Base address + 50h offset + (4d × i), where i=0d to 3d

USBPHYx_DEBUGn field descriptions

Field	Description
31 RSVD3	Reserved.
30 CLKGATE	Gate Test Clocks. Clear to 0 for running clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated.
29 HOST_RESUME_DEBUG	Choose to trigger the host resume SE0 with HOST_FORCE_LS_SE0 = 0 or UTMI_SUSPEND = 1.
28–25 SQUELCHRESETLENGTH	Duration of RESET in terms of the number of 480-MHz cycles.
24 ENSQUELCHRESET	Set bit to allow squelch to reset high-speed receive.
23–21 RSVD2	Reserved.
20–16 SQUELCHRESETCOUNT	Delay in between the detection of squelch to the reset of high-speed RX.
15–13 RSVD1	Reserved.
12 ENTX2RXCOUNT	Set this bit to allow a countdown to transition in between TX and RX.
11–8 TX2RXCOUNT	Delay in between the end of transmit to the beginning of receive. This is a Johnson count value and thus will count to 8.
7–6 RSVD0	Reserved.
5–4 ENHSTPULLDOWN	Set bit 5 to 1 to override the control of the USB_DP 15-KOhm pulldown. Set bit 4 to 1 to override the control of the USB_DM 15-KOhm pulldown. Clear to 0 to disable.
3–2 HSTPULLDOWN	Set bit 3 to 1 to pull down 15-KOhm on USB_DP line. Set bit 2 to 1 to pull down 15-KOhm on USB_DM line. Clear to 0 to disable.
1 DEBUG_INTERFACE_HOLD	Use holding registers to assist in timing for external UTMI interface.
0 OTGIDPIOLOCK	Once OTG ID from USBPHYx_STATUS_OTGID_STATUS, use this to hold the value. This is to save power for the comparators that are used to determine the ID status.

58.3.7 UTMI Debug Status Register 0 (USBPHYx_DEBUG0_STATUS)

The UTMI Debug Status Register 0 holds multiple views for counters and status of state machines. This is used in conjunction with the USBPHYx_DEBUG1_DBG_ADDRESS field to choose which function to view. The default is described in the bit fields below and is used to count errors.

Address: Base address + 60h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	SQUELCH_COUNT						UTMI_RXERROR_FAIL_COUNT						LOOP_BACK_FAIL_COUNT																				
W	[Write Mask]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHYx_DEBUG0_STATUS field descriptions

Field	Description
31–26 SQUELCH_COUNT	Running count of the squelch reset instead of normal end for HS RX.
25–16 UTMI_RXERROR_FAIL_COUNT	Running count of the UTMI_RXERROR.
LOOP_BACK_FAIL_COUNT	Running count of the failed pseudo-random generator loopback. Each time entering testmode, counter goes to 900D and will count up for every detected packet failure in digital/analog loopback tests.

58.3.8 UTMI Debug Status Register 1 (USBPHYx_DEBUG1n)

Chooses the muxing of the debug register to be shown in USBPHYx_DEBUG0_STATUS.

Address: Base address + 70h offset + (4d × i), where i=0d to 3d

USBPHYx_DEBUG1n field descriptions

Field	Description
31–15 RSVD1	Reserved.
14–13 ENTAILADJVD	Delay increment of the rise of squelch: 00 = Delay is nominal 01 = Delay is +20% 10 = Delay is -20% 11 = Delay is -40%
RSVD0	Reserved. Note: This bit should remain clear.

58.3.9 UTMI RTL Version (USBPHYx_VERSION)

Fields for RTL Version.

Address: Base address + 80h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	MAJOR								MINOR								STEP																
W	[Shaded]																																
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBPHYx_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
STEP	Fixed read-only value reflecting the stepping of the RTL version.

58.4 USB Analog Memory Map/Register Definition

USB_ANALOG memory map

58.4.1 USB VBUS Detect Register (USB_ANALOG_USB1_VBUS_DETECTn)

This register defines controls for USB VBUS detect.

Address: 0h base + 1A0h offset + (4d × i), where i=0d to 3d

USB_ANALOG_USB1_VBUS_DETECTn field descriptions

Field	Description
31–28 -	This field is reserved. Reserved.
27 CHARGE_VBUS	USB OTG charge VBUS.
26 DISCHARGE_VBUS	USB OTG discharge VBUS.
25–21 -	This field is reserved. Reserved.
20 VBUSVALID_PWRUP_CMPS	Powers up comparators for vbus_valid detector.
19–3 -	This field is reserved. Reserved.
VBUSVALID_THRESH	Set the threshold for the VBUSVALID comparator. This comparator is the most accurate method to determine the presence of 5v, and includes hystersis to minimize the need for software debounce of the detection. This comparator has ~50mV of hystersis to prevent chattering at the comparator trip point. 000 4V0 — 4.0V

Table continues on the next page...

USB_ANALOG_USB1_VBUS_DETECT n field descriptions (continued)

Field	Description
001	4V1 — 4.1V
010	4V2 — 4.2V
011	4V3 — 4.3V
100	4V4 — 4.4V (default)
101	4V5 — 4.5V
110	4V6 — 4.6V
111	4V7 — 4.7V

58.4.2 USB Charger Detect Register (USB_ANALOG_USB1_CHRG_DETECT n)

This register defines controls for USB charger detect.

Address: 0h base + 1B0h offset + (4d × i), where i=0d to 3d

USB_ANALOG_USB1_CHRG_DETECT n field descriptions

Field	Description
31–24 -	This field is reserved. Reserved.

Table continues on the next page...

USB_ANALOG_USB1_CHRG_DETECT n field descriptions (continued)

Field	Description
23 -	This field is reserved. Reserved.
22–21 -	This field is reserved. Reserved.
20 EN_B	Control the charger detector. 0 ENABLE — Enable the charger detector. 1 DISABLE — Disable the charger detector.
19 CHK_CHRG_B	0 CHECK — Check whether a charger (either a dedicated charger or a host charger) is connected to USB port. 1 NO_CHECK — Do not check whether a charger is connected to the USB port.
18 CHK_CONTACT	0 NO_CHECK — Do not check the contact of USB plug. 1 CHECK — Check whether the USB plug has been in contact with each other
-	This field is reserved. Reserved.

58.4.3 USB VBUS Detect Status Register (USB_ANALOG_USB1_VBUS_DETECT_STAT)

This register defines fields for USB VBUS Detect status.

Address: 0h base + 1C0h offset = 1C0h

USB_ANALOG_USB1_VBUS_DETECT_STAT field descriptions

Field	Description
31–4 -	This field is reserved. Reserved.

Table continues on the next page...

USB_ANALOG_USB1_VBUS_DETECT_STAT field descriptions (continued)

Field	Description
3 VBUS_VALID	VBus valid for USB OTG. This bit is a read only version of the state of the analog signal. It can not be overwritten by software.
2 AVALID	Indicates VBus is valid for a A-peripheral. This bit is a read only version of the state of the analog signal. It can not be overwritten by software.
1 BVALID	Indicates VBus is valid for a B-peripheral. This bit is a read only version of the state of the analog signal. It can not be overwritten by software.
0 SESSEND	<p>Session End for USB OTG. This bit is a read only version of the state of the analog signal. It can not be overwritten by software like the SESSEND bit below.</p> <p>NOTE: This bit's default value depends on whether VDD5V is present, 0 if VDD5V is present, 1 if VDD5V is not present.</p>

58.4.4 USB Charger Detect Status Register (USB_ANALOG_USB1_CHRG_DETECT_STAT)

This register defines fields for USB charger detect status.

Address: 0h base + 1D0h offset = 1D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USB_ANALOG_USB1_CHRG_DETECT_STAT field descriptions

Field	Description
31–4 -	This field is reserved. Reserved.
3 DP_STATE	DP line state output of the charger detector.
2 DM_STATE	DM line state output of the charger detector.
1 CHRG_DETECTED	State of charger detection. This bit is a read only version of the state of the analog signal. 0 CHARGER_NOT_PRESENT — The USB port is not connected to a charger. 1 CHARGER_PRESENT — A charger (either a dedicated charger or a host charger) is connected to the USB port.
0 PLUG_CONTACT	State of the USB plug contact detector. 0 NO_CONTACT — The USB plug has not made contact. 1 GOOD_CONTACT — The USB plug has made good contact.

58.4.5 USB Misc Register (USB_ANALOG_USB1_MISCN)

This register defines controls for USB.

Address: 0h base + 1F0h offset + (4d × i), where i=0d to 3d

USB_ANALOG_USB1_MISC_n field descriptions

Field	Description
31 -	This field is reserved. Reserved.
30 EN_CLK_UTMI	Enables the clk to the UTMI block.
29–2 -	This field is reserved. Reserved.
1 EN_DEGLITCH	Enable the deglitching circuit of the USB PLL output.
0 HS_USE_EXTERNAL_R	Use external resistor to generate the current bias for the high speed transmitter. This bit should not be changed unless recommended by Freescale.

58.4.6 USB VBUS Detect Register (USB_ANALOG_USB2_VBUS_DETECT_n)

This register defines controls for USB VBUS detect.

Address: 0h base + 200h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
3 VBUS_VALID	VBus valid for USB OTG. This bit is a read only version of the state of the analog signal. It can not be overwritten by software.
2 AVALID	Indicates VBus is valid for a A-peripheral. This bit is a read only version of the state of the analog signal. It can not be overwritten by software.
1 BVALID	Indicates VBus is valid for a B-peripheral. This bit is a read only version of the state of the analog signal. It can not be overwritten by software.
0 SESSEND	<p>Session End for USB OTG. This bit is a read only version of the state of the analog signal. It can not be overwritten by software like the SESSEND bit below.</p> <p>NOTE: This bit's default value depends on whether VDD5V is present, 0 if VDD5V is present, 1 if VDD5V is not present.</p>

58.4.9 USB Charger Detect Status Register (USB_ANALOG_USB2_CHRG_DETECT_STAT)

This register defines fields for USB charger detect status.

Address: 0h base + 230h offset = 230h

USB_ANALOG_USB2_CHRG_DETECT_STAT field descriptions

Field	Description
31–4 -	This field is reserved. Reserved.
3 DP_STATE	DP line state output of the charger detector.
2 DM_STATE	DM line state output of the charger detector.
1 CHRG_DETECTED	State of charger detection. This bit is a read only version of the state of the analog signal. 0 CHARGER_NOT_PRESENT — The USB port is not connected to a charger. 1 CHARGER_PRESENT — A charger (either a dedicated charger or a host charger) is connected to the USB port.
0 PLUG_CONTACT	State of the USB plug contact detector. 0 NO_CONTACT — The USB plug has not made contact. 1 GOOD_CONTACT — The USB plug has made good contact.

58.4.10 USB Misc Register (USB_ANALOG_USB2_MISCn)

This register defines controls for USB.

Address: 0h base + 250h offset + (4d × i), where i=0d to 3d

USB_ANALOG_USB2_MISC_n field descriptions

Field	Description
31 -	This field is reserved. Reserved.
30 EN_CLK_UTMI	Enables the clk to the UTMI block.
29–2 -	This field is reserved. Reserved.
1 EN_DEGLITCH	Enable the deglitching circuit of the USB PLL output.
0 HS_USE_EXTERNAL_R	Use external resistor to generate the current bias for the high speed transmitter. This bit should not be changed unless recommended by Freescale.

58.4.11 Chip Silicon Version (USB_ANALOG_DIGPROG)

The DIGPROG register returns the digital program ID for the silicon.

For silicon revision 1.0, USB_ANALOG_DIGPROG = 0x0064_0000

For silicon revision 1.1, USB_ANALOG_DIGPROG = 0x0064_0001

For silicon revision 1.2, USB_ANALOG_DIGPROG = 0x0064_0002

Address: 0h base + 260h offset = 260h

Chapter 59

Ultra Secured Digital Host Controller (uSDHC)

59.1 Overview

The Ultra Secured Digital Host Controller (uSDHC) provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in [Figure 59-1](#).

The uSDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards.

It handles the SD/SDIO/MMC protocols at the transmission level.

The following are brief descriptions of the cards supported by the uSDHC:

The Multi Media Card (MMC) is a universal low cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous MMC cards were based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly-emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward-compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into Memory card, I/O card and Combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, the following figure does not show cards with reduced size or mini cards.

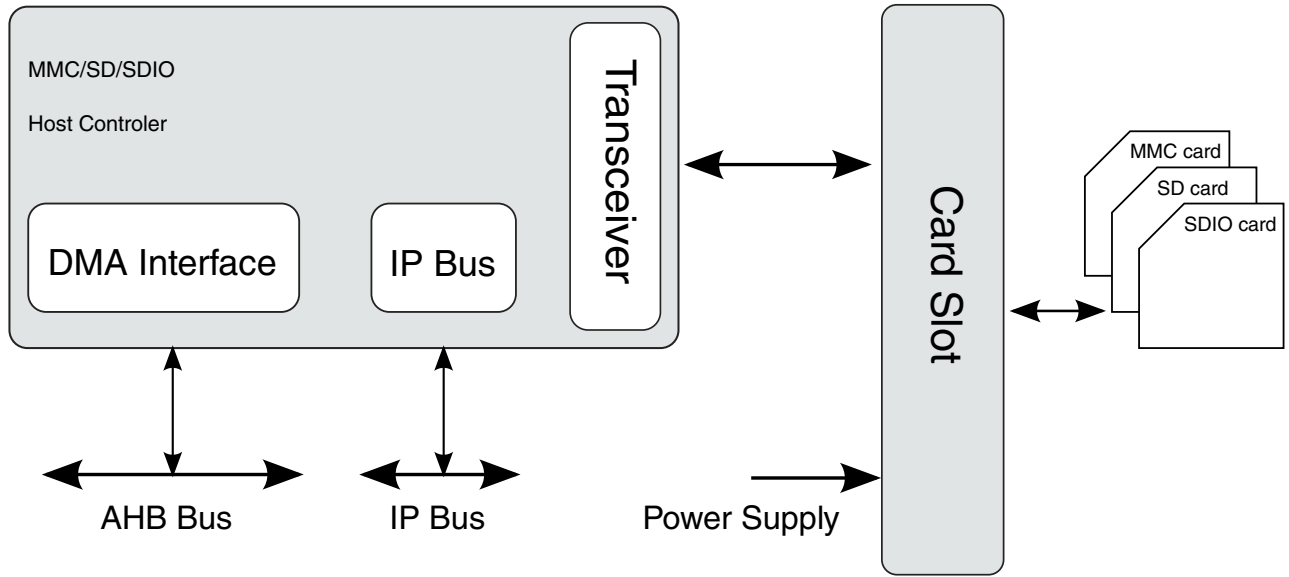

Figure 59-1. System Connection of the uSDHC

Figure 59-2. ultra Secure Digital Host Controller Block Diagram

59.1.1 Features

The features of the uSDHC module include the following:

- Conforms to the SD Host Controller Standard Specification version 3.0
- Compatible with the MMC System Specification version 4.2/4.3/4.4/4.41/4.5
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 208 MHz
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes
 - Up to 832 Mbps of data transfer for SDIO cards using 4 parallel data lines in SDR(Single Data Rate) mode
 - Up to 400 Mbps of data transfer for SDIO card using 4 parallel data lines in DDR(Dual Data Rate) mode
 - Up to 832 Mbps of data transfer for SDXC cards using 4 parallel data lines in SDR(Single Data Rate) mode
 - Up to 400 Mbps of data transfer for SDXC card using 4 parallel data lines in DDR(Dual Data Rate) mode
 - Up to 416 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR(Single Data Rate) mode
 - Up to 832 Mbps of data transfer for MMC cards using 8 parallel data lines in DDR(Dual Data Rate) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal and external DMA capabilities
- Support voltage selection by configuring vendor specific register bit
- Supports Advanced DMA to perform linked memory access

59.1.2 Modes and Operations

59.1.2.1 Data transfer Modes

The uSDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification Mode (up to 400 kHz)
- MMC full speed mode (up to 26 MHz)
- MMC high speed mode (up to 52 MHz)
- MMC HS200 mode (up to 200 MHz)
- MMC DDR mode (52 MHz both edges)
- SD/SDIO full speed mode (up to 25 MHz)
- SD/SDIO high speed mode (up to 50 MHz)
- SD/SDIO UHS-I mode (up to 208 MHz in SDR mode, up to 50 MHz in DDR mode)

59.2 External Signals

The following table describes the external signals of USDHC:

Table 59-1. USDHC External Signals

Signal	Description	Pad	Mode	Direction
SD1_CD_B	Card detection pin If not used(for the embedded memory),tie low to indicate there is a card attached.	CSI_DATA05	ALT8	I
		GPIO1_IO03	ALT4	
		UART1_RTS_B	ALT2	
SD1_CLK	Clock for MMC/SD/SDIO card	SD1_CLK	ALT0	O
SD1_CMD	CMD line connect to card	SD1_CMD	ALT0	IO
SD1_DATA0	DATA0 line in all modes Also used to detect busy sta	SD1_DATA0	ALT0	IO
SD1_DATA1	DATA1 line in 4/8-bit mode Also used to detect interrupt in 1/4-bit mode	SD1_DATA1	ALT0	IO
SD1_DATA2	DATA2 line or Read Wait in 4-bit mode Read Wait in 1-bit mode	SD1_DATA2	ALT0	IO

Table continues on the next page...

Table 59-1. USDHC External Signals (continued)

		UART1_CTS_B	ALT8	

59.2.1 Signals Overview

The uSDHC has 14 associated I/O signals.

- The CLK is an internally generated clock used to drive the MMC, SD, SDIO cards.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the uSDHC and the card.

Clocks

- The CD and WP are card detection and write protection signals directly routed from the socket. These two signals are active low (0). A low on CD# means that a card is inserted, and a high on WP means that the write protect switch is active.
- LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.
- RST is an output signal used to reset the MMC card.
- VSELECT is an output signal used to change the voltage of the external power supplier.

CD, WP, LCTL, RST and VSELECT are all optional for system implementation. If the uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.

59.3 Clocks

The table found here describes the clock sources for uSDHC.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 59-2. uSDHC Clocks

Clock name	Clock Root	Description
hclk	ahb_clk_root	AHB bus clock
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_perclk	usdhc_clk_root	Base clock
ipg_clk_s	ipg_clk_root	Peripheral access clock for register accesses

59.4 Functional Description

The following sections provide a brief functional description of the major system blocks, including the Data Buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

59.4.1 Data Buffer

The uSDHC uses one configurable data buffer to transfer data between the system bus (IP Bus or AHB Bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock).

The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable and can be from 1 to 128 words. The burst lengths for read and write are also configurable and can be from 1 to 31 words.

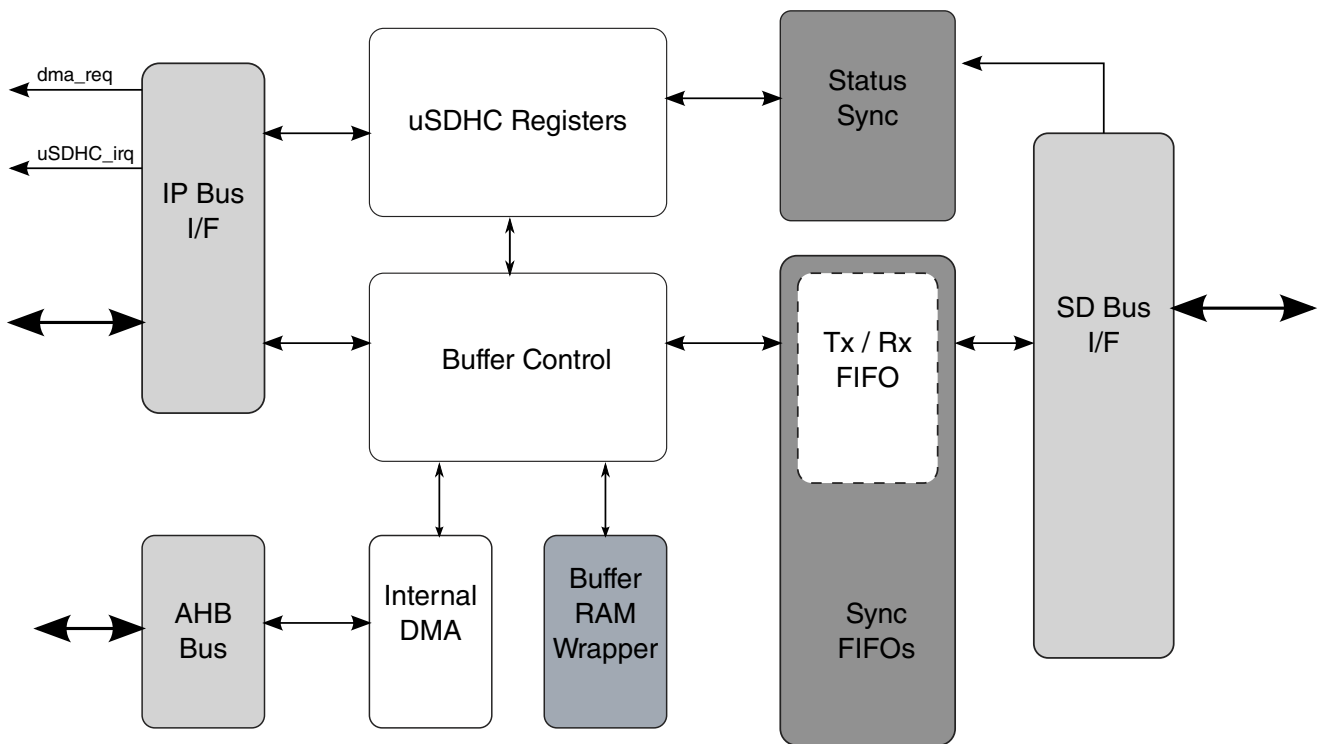

Figure 59-3. uSDHC Buffer Scheme

There are 3 transfer modes to access the data buffer:

- CPU polling mode:
 - For a host read operation, when the number of words received in the buffer meets or exceeds the `RD_WML` watermark value, by polling the `BRR` bit, the Host Driver can read the Buffer Data Port register to fetch the amount of words set in the `RD_WML` register from the buffer. The write operation is similar.
- External DMA mode:
 - For a read operation, when there are more words received in the buffer than the amount set in the `RD_WML` register, a DMA request is sent out to inform the external DMA to fetch the data. The request will be immediately de-asserted when there is an access on the Buffer Data Port register. If the number of words

Functional Description

in the buffer after the current burst meets or exceeds RD_WML value, the DMA request is asserted again. For instance, if there are twice as many words in the buffer as there are in the RD_WML value, there are two successive DMA requests with only one cycle of de-assertion between. The write operation is similar. Note the accesses CPU polling mode and external DMA mode both use the IP bus, and if the external DMA is enabled, in both modes an external DMA request is sent when the buffer is ready.

- Internal DMA mode (includes simple and advanced DMA accesses):
 - The internal DMA access, either by simple or advanced DMA, is over the AHB bus. For internal DMA access mode, the external DMA request will never be sent out.

For a read operation, when there are more words in the buffer than the amount set in the RD_WML register, the internal DMA starts fetching data over the AHB bus. Except for INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

- Burst length configured in the burst length field of the Watermark Level register
- Watermark Level boundary
- Block size boundary
- Data boundary configured in the current descriptor (if the ADMA is active)
- 1 Kbyte address boundary defined in the AHB protocol

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, byte order is swapped before the data is stored in the buffer.

Figure 59-4. Data Swap between System Bus and uSDHC Data Buffer in Byte Little Endian Mode

Figure 59-5. Data Swap between System Bus and uSDHC Data Buffer in Half Word Big Endian Mode

59.4.1.1 Write Operation Sequence

There are three ways to write data into the buffer when the user transfers data to the card:

- External DMA through the uSDHC DMA request signal
- Processor core polling through the BWR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, (the DMAEN bit in the Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR_WML register, and is ready for receiving new data. At the same time, the uSDHC sets the BWR bit. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the write operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

The uSDHC will not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the Host System does not write data in time, the uSDHC will stop the CLK to avoid the data buffer under-run situation.

59.4.1.2 Read Operation Sequence

There are three ways to read data from the buffer when the user transfers data to the card:

- External DMA through the uSDHC DMA request signal
- Processor core polling through the BRR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, that is available and ready for system fetching data. At the same time, the uSDHC sets the BRR bit. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the read operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

For any write transfer mode, the uSDHC will not start data transmission until the number of words set in the RD_WML register are in the buffer. If the buffer is full and the Host System does not read data in time, the uSDHC will stop the CLK to avoid the data buffer over-run situation.

59.4.1.3 Data Buffer and Block Size

The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. In the uSDHC, the only data buffer can hold up to 128 words (32-bit) and the watermark levels for write and read can be configured accordingly.

For both read and write, the watermark level can be from 1 to 128 words. For both read and write the burst length can be from 1 to 31 words. The Host Driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned) stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write two times for each block. For each block the ending byte will be abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

59.4.1.4 Dividing Large Data Transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the Host Driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the dividing of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size up to 64 bytes. Although the uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than 64 bytes, so the data must be divided (see example below).

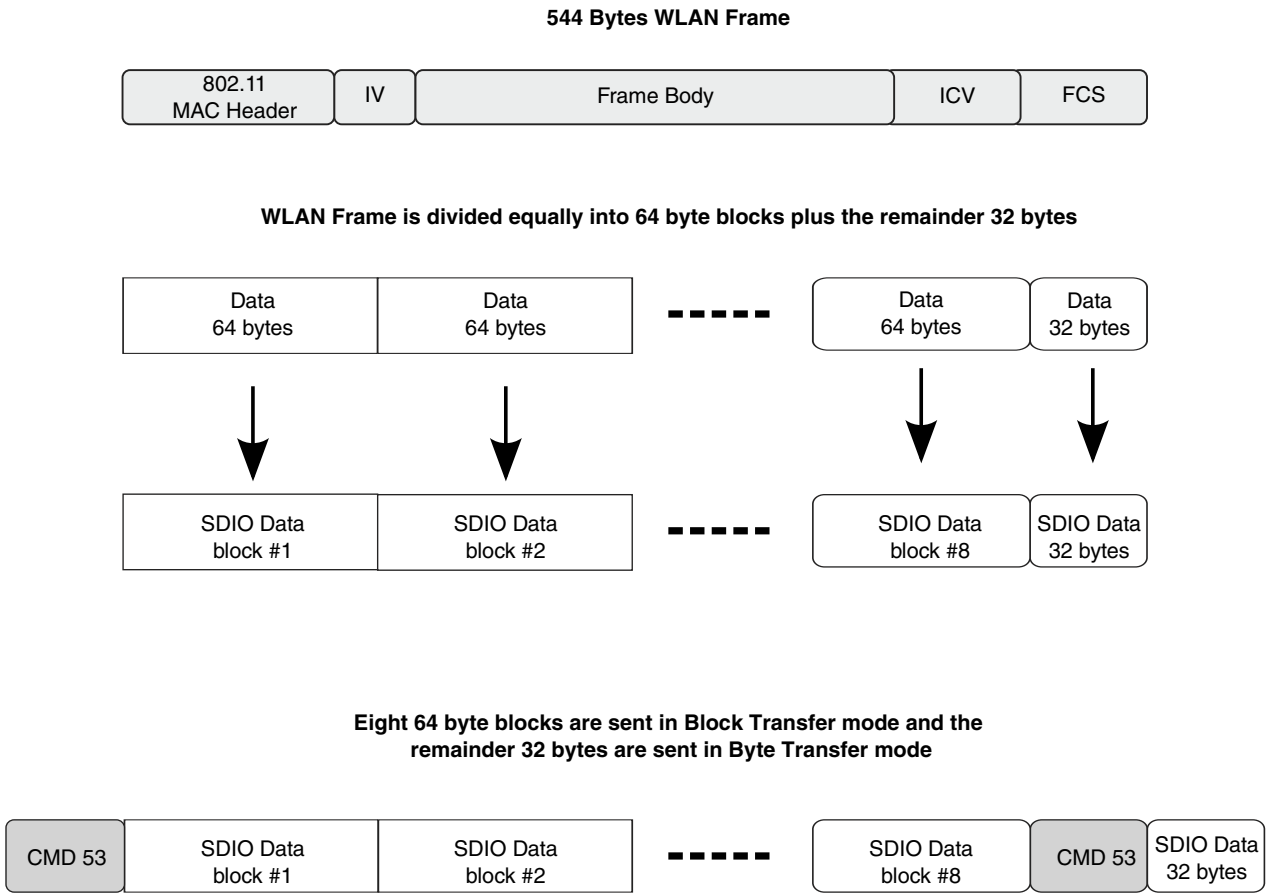

Figure 59-6. Example for Dividing Large Data Transfers

59.4.1.5 External DMA Request

When the internal DMA is not in use and external DMA is enabled, the Data Buffer will generate a DMA request to the system. During a write operation, when the number of WR_WML words can be held in the buffer free space, the signal uSDHC_dreq_b is asserted to 0, informing the Host System of a DMA write.

The BWR bit in the Interrupt Status register is also set, as long as the BWRSEN bit in the Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Port register are made while the buffer's free space can't meet the watermark condition (free space > write watermark level).

On read operation, when the number of RD_WML words are already in the buffer, the signal uSDHC_dreq_b is asserted to 0, informing the Host System for a DMA read. The BRR bit in the Interrupt Status register is also set, as long as the BRRSEN bit in the

Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Port register are made while the buffer's data can't meet the watermark condition (the number of data in buffer > read watermark level).

If the DMA burst length can't change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring the block may cause buffer under-run (read operation) or over-run (write operation). For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of two between 1 and 128. For processor core polling access there is no such issue, as the last access in the block transfer can be controlled by software. The watermark level can be any value, even larger than the block size (but no greater than 128 words) because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The uSDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level should be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of words. For this case, the BLKSIZE bits of the Block Attribute register will be set as 1fh. For the CPU polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the uSDHC will also set the BWR or BRR bits when the remaining data does not violate data buffer. See [DMA Burst Length](#) for more details about the dynamic watermark level of the data buffer.

For the above example, even though 8 words are transferred via the Data Port register, the uSDHC will transfer only 31 bytes over the SD Bus, as required by the BLKSIZE bits. In this data transfer, with non-word aligned block size, the endian mode should be set cautiously or invalid data will be transferred to and from the card.

59.4.2 DMA AHB Interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the `uSDHC_dreq_b` will not be asserted during the transfer, but the BWR and BRR bits will be set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register.

See the figure below for an illustration of the DMA AHB interface block.

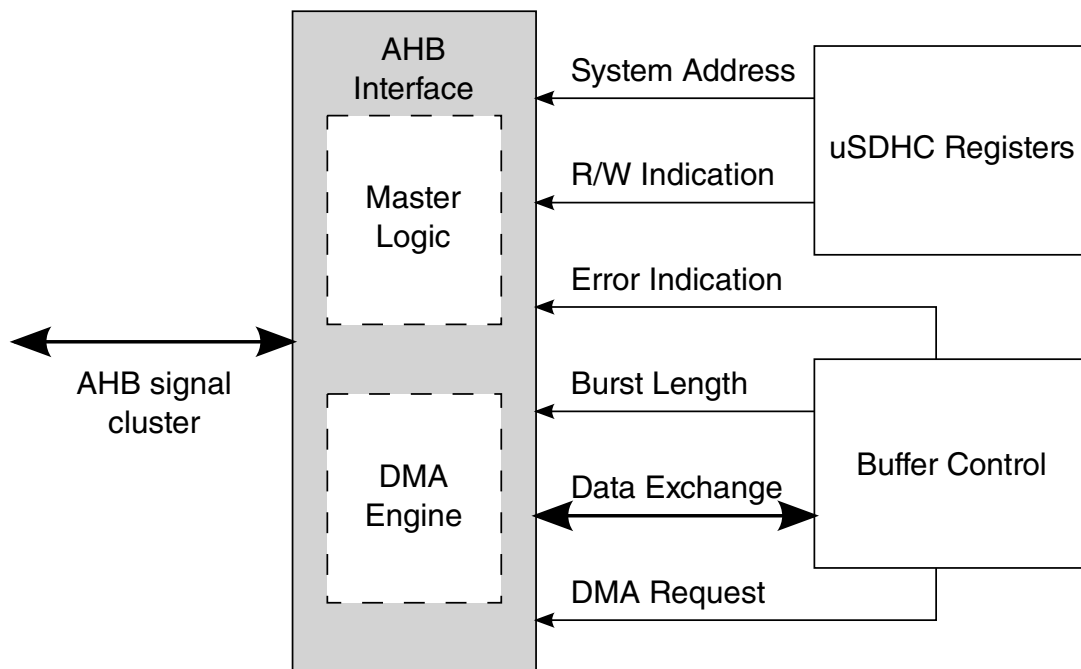

Figure 59-7. DMA AHB Interface Block

59.4.2.1 Internal DMA Request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the Data Buffer block will send a DMA request to AHB interface. Meanwhile, the external DMA request signal (`uSDHC_dreq_b`) is disabled.

The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to the uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The Data Buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA,

the Data Buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer (which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to send for the current block is $(31 - 6 * 4) / 4 = 2$. The uSDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuffed byte.

59.4.2.2 DMA Burst Length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block.

See the example in [Internal DMA Request](#). After 6 words are read, the burst length will be 2 words, then the next burst length will be 6 words. This is because the next block starts, which is 31 bytes, more than 6 words. The Host Driver may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

59.4.2.3 AHB Master Interface

It is possible that the internal AHB DMA engine could fail during the data transfer. Upon detection of an AHB bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register will be generated to host CPU to report a bus error condition.

Once the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and re-start the transfer from this address to recover the corrupted block. DMA operation will resume when the interrupt is serviced by software.

59.4.2.4 ADMA Engine

In the SD Host Controller Standard, a new DMA transfer algorithm called the ADMA (Advanced DMA) is defined. For Simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the Host Driver.

The ADMA defines the programmable descriptor table in the system memory. The Host Driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized since the Host MCU intervention would not be needed during long DMA based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in Host Controller. ADMA1 can support data transfer of 4KB aligned data in system memory. ADMA2 improves the restriction so that data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors define in SD Host Controller Standard, and if 'End' flag is detected in the descriptor, ADMA will stop after this descriptor is processed.

59.4.2.4.1 ADMA Concept and Descriptor Format

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Set data length descriptor.
- Set data address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Rsv descriptor.
- Set data length & address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

See [Figure 59-8](#) for the format of the descriptor table for ADMA1.

Figure 59-11 explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it will ignore the high 32-bit. Address field shall be set on word aligned(lower 2-bit is always set to 0). Data length is in byte unit.

ADMA will start read/write operation after it reaches the Tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last Set type descriptor before Tran type descriptor. Every Tran type will trigger a transfer, and the transfer data length is extracted from the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length will be the value for previous transfer, or 0 if no Set descriptor is ever met.

For ADMA2, Tran type descriptor contains both data length and transfer data address, so only a Tran type descriptor can start a data transfer

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 59-8. Format of the ADMA1 Descriptor Table

Functional Description

System Address Register points to the head node of Descriptor Table

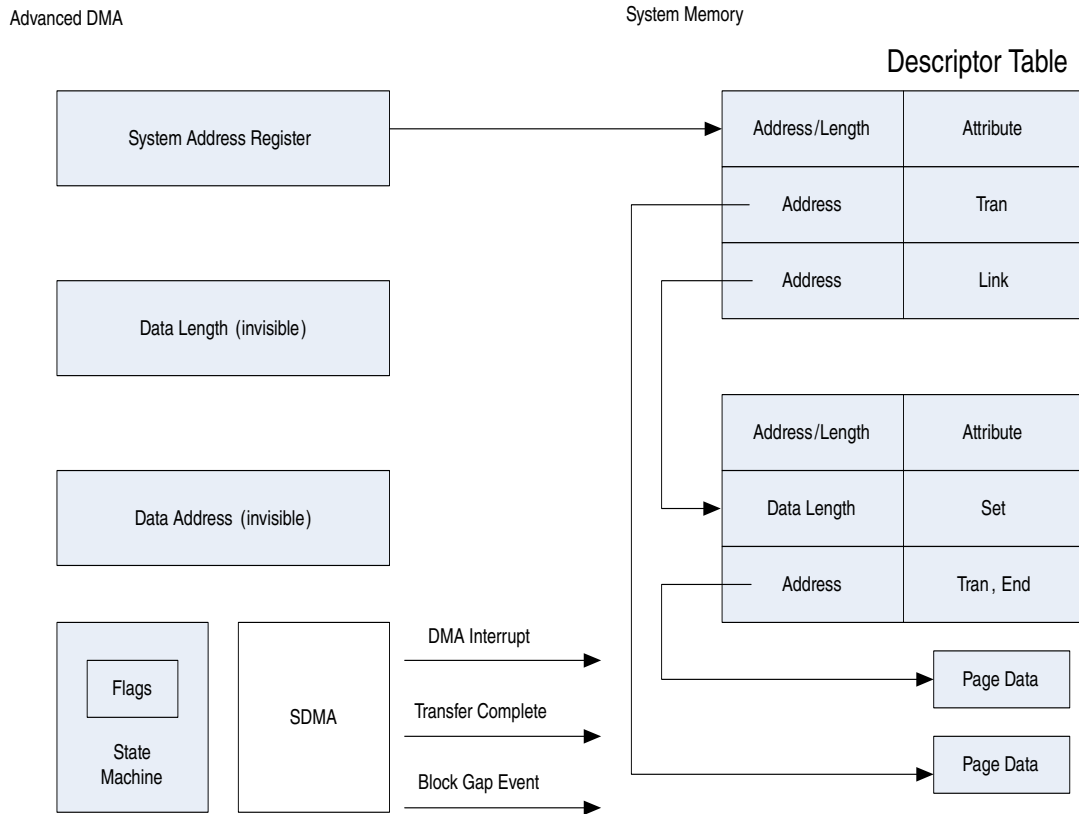

Figure 59-9. Concept and Access Method of ADMA1 Descriptor Table

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 59-10. Format of the ADMA2 Descriptor Table

Functional Description

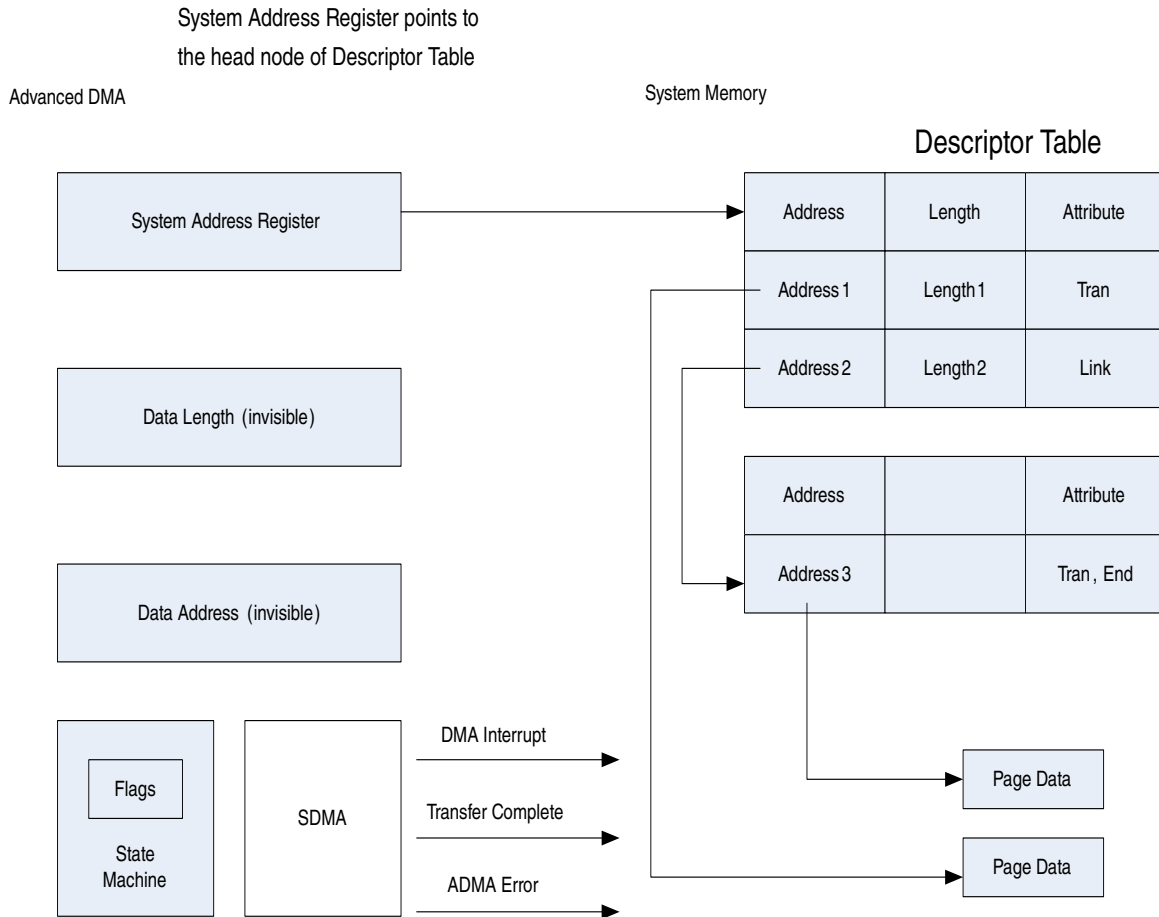

Figure 59-11. Concept and Access Method of ADMA2 Descriptor Table

59.4.2.4.2 ADMA Interrupt

If the interrupt flag descriptor is set, ADMA will generate an interrupt according to various types of descriptors:

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

59.4.2.4.3 ADMA Error

The ADMA will stop whenever any error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

An ADMA descriptor error will be generated when it fails to detect a 'Valid' flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the 'Interrupt' flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

When BLKCNTEN bit is not set, then whole data length set in descriptor should be a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors will occur.

59.4.3 Register Bank with IP Bus Interface

Register accesses via the IP Bus interface are actually on the Register Bank.

See [Figure 59-12](#) below for the block diagram.

Functional Description

Figure 59-12. Register Bank Diagram

Only 32-bit access is allowed, and no partial read / write is supported, thus all accesses are word aligned.

59.4.3.1 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs.

The SD Protocol Unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD Protocol Unit consists of four sub modules:

1. SD control misc.

2. Command control.
3. Data control.
4. Clock control

59.4.3.2 SD control misc

In the SD control misc unit, the card detect(include the CD_B and DATA3 used as Card Detection), write protection and card interrupt are implemented.

This module monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the Register Bank. The driver can use this for debug purposes.

The module also detects the WP (Write Protect) line. If WP is active, writes to the register bank will be ignored.

This module also drives the LCTL output signal when the LCTL bit is set by the driver.

59.4.3.3 SD Clock control

If the internal data buffer is near full(for read) or near empty(for write), the SD clock must be gated off to avoid buffer over/under-run, this module will assert the gate of the output SD clock to shut the clock off. After the buffer has space(for read) or has data(for write), the clock gate of this module will open and the SD clock will be active again.

59.4.3.4 Command control

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC Shift Register.

Functional Description

Figure 59-13. Command CRC Shift Register

The CRC polynomials for the CMD are as follows:

Generator polynomial: $G(x) = x^7 + x^3 + 1$
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$
 $\text{CRC}[6:0] = \text{Remainder} [(M(x) * x^7) / G(x)]$

59.4.3.5 Data control

The Data Agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line, and generates the Read Wait state by the request from the Transceiver.

The CRC polynomials for the DATA are as follows:

Generator polynomial: $G(x) = x^{16} + x^{12} + x^5 + 1$
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$
 $\text{CRC}[15:0] = \text{Remainder} [(M(x) * x^{16}) / G(x)]$

59.4.4 Clock & Reset Manager

This module controls all the reset signals within the uSDHC.

There are four kinds of reset signals within uSDHC:

1. Hardware reset.
2. Software reset for all logic.
3. Software reset for the data logic.
4. Software reset for the command logic.

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

59.4.5 Clock Generator

The Clock Generator generates the card CLK by peripheral source clock in two stages.

Refer to the figure below for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

Figure 59-14. Two Stages of the Clock Divider

The first divisor stage (controlled by `uSDHCx_SYS_CTRL[DVS]`) outputs an intermediate clock (DIV), which can be Base, Base/2, Base/3, ..., or Base/16.

The second divisor stage (controlled by `uSDHCx_SYS_CTRL[SDCLKFS]`) outputs the actual internal working clock (card_clk). This clock is the driving clock for all sub modules of the SD Protocol Unit, and the sync FIFOs (see Figure 67-3) to synchronize with the data rate from the internal data buffer.

Please note, in SDR mode and DDR mode, the CLK are different.

- In SDR mode, CLK is equal to the internal working clock(card_clk).
- In DDR mode, CLK is equal to the card_clk/2.

59.4.6 SDIO Card Interrupt

Information on Interrupts in 1-bit Mode, Interrupts in 4-bit Mode, and Card Interrupt Handling are detailed in the sections below.

59.4.6.1 Interrupts in 1-bit Mode

In this case the DATA1 pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DATA1 low from the SDIO card, until the interrupt service is finished to clear the interrupt.

59.4.6.2 Interrupt in 4-bit Mode

Since the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will only be sent by the card and recognized by the host during a specific time. This is known as the Interrupt Period. The uSDHC will only sample the level on Pin 8 during the Interrupt Period. At all other times, the host will ignore the level on Pin 8, and treat it as the data signal. The definition of the Interrupt Period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the Interrupt Period becomes active two clock cycles after the completion of a data packet. This Interrupt Period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the Interrupt Period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the Interrupt Period. For this case, the Interrupt Period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line will be held low for one clock cycle with the last clock cycle pulling DATA1 high. On completion of the Interrupt Period, the card releases the DATA1 line into the high Z state. The uSDHC samples the DATA1 during the Interrupt Period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

59.4.6.3 Card Interrupt Handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, the uSDHC clears the interrupt request to the Host System. The Host Driver should clear this bit before servicing the SDIO Interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. In 1-bit mode, the uSDHC will detect the SDIO Interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the Interrupt Period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status has been set, and the Host Driver needs to service this interrupt, so the SDIO bit in the Interrupt Control Register of SDIO card will be cleared. This is required to clear

the SDIO interrupt status latched in the uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The Host Driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1, and the uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

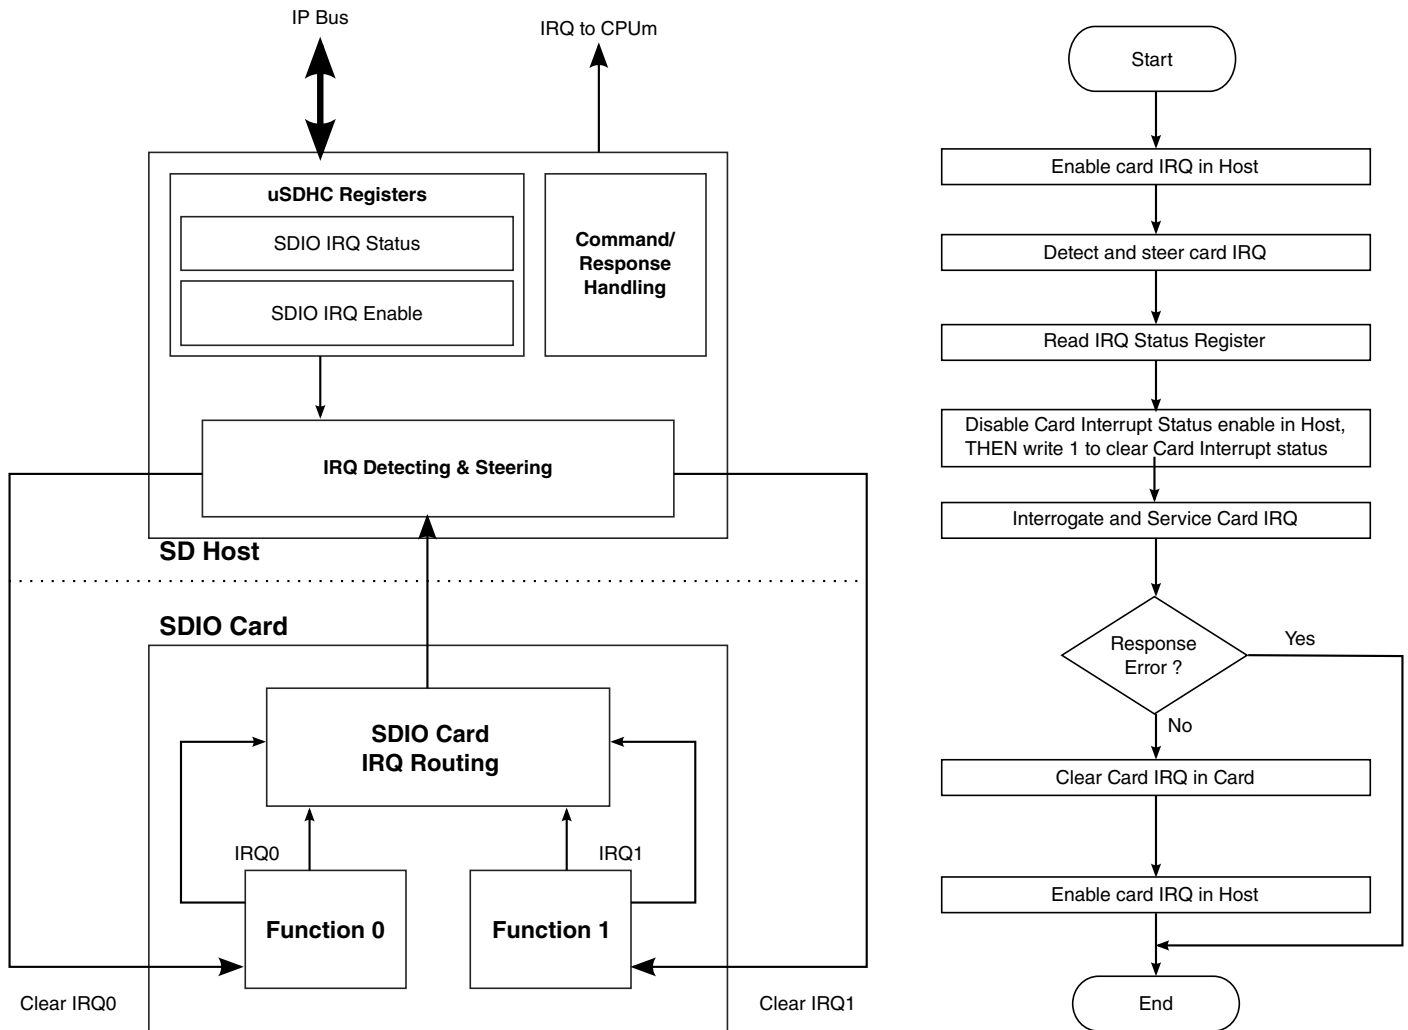

Figure 59-15. Card Interrupt Scheme and Card Interrupt Detection and Handling Procedure

59.4.7 Card Insertion and Removal Detection

The uSDHC uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DATA3 will be pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, the uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, the uSDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

59.4.8 Power Management and Wake Up Events

When there is no operation between the uSDHC and the card through the SD bus, the user can completely disable the ipg_clk and ipg_perclk in the chip level clock control module to save power. When the user needs to use the uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the uSDHC are disabled, for instance, when the system is in low power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC can generate these interrupt even when there are no clocks enabled. The three interrupts which can be used as wake up events are:

1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

The uSDHC offers a power management feature. By clearing the clock enabled bits in the System Control Register, the clocks are gated in the low position to the uSDHC. For maximum power saving, the user can disable all the clocks to the uSDHC when there is no operation in progress.

These three wake up events (or wakeup interrupts) can also be used to wake up the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to the uSDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be

set. Refer to [Protocol Control \(uSDHC_PROT_CTRL\)](#) for more information on the uSDHC Protocol Control register.

59.4.8.1 Setting Wake Up Events

For the uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters sleep mode.

Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

59.4.9 MMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature which requires hardware support. There are two types of fast boot mode, boot operation, and alternative boot operation in the eMMC4.3 specification. Each type also has with-acknowledge and without-acknowledge modes.

In boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFFFA (optional for slave), before issuing CMD1.

NOTE

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

59.4.9.1 Boot operation

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If the CMD line is held LOW for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Functional Description

Within 1 second after the CMD line goes LOW, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line LOW to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes LOW. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode with the CMD line HIGH.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

Figure 59-16. MultiMediaCard state diagram (normal boot mode)

59.4.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

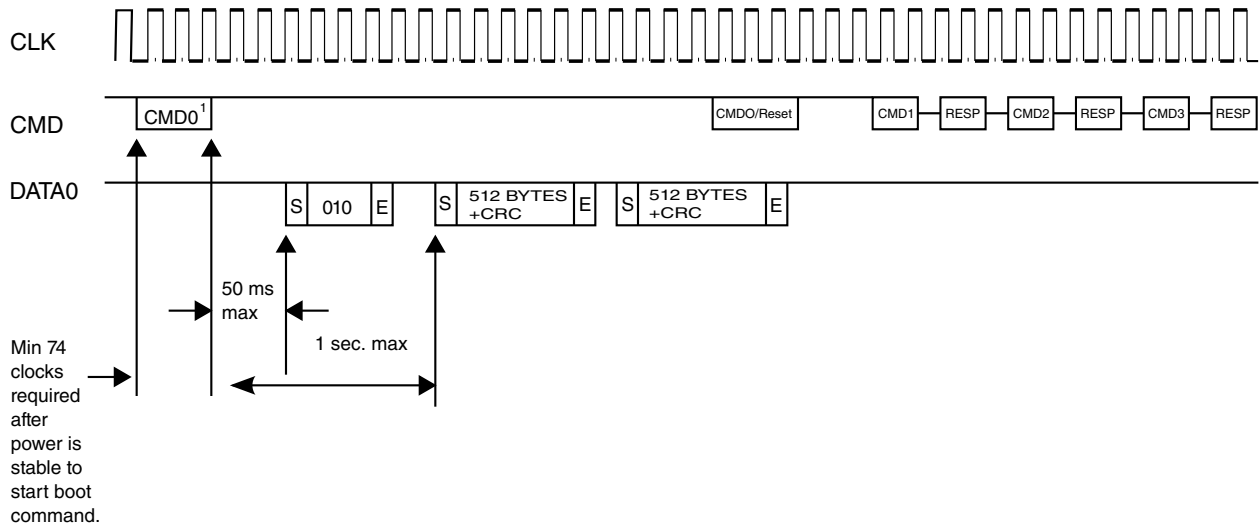

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFFFA is received. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

NOTE 1. CMD0 with argument 0xFFFFFFFF

Figure 59-17. MultiMediaCard state diagram (alternative boot mode)

59.5 Initialization/Application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, ALL_SEND_CID. In Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to [Commands for MMC/SD/SDIO](#) for the commands of bc and bcr categories.

After the Broadcast command CMD3 is issued, the cards enter standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads will turn to push-pull mode, to have the driving capability for maximum frequency operation. Refer to [Commands for MMC/SD/SDIO](#) for the commands of ac and adtc categories.

59.5.1 Command Send & Response Receive Basic Operation

Assuming the data type WORD is an unsigned 32-bit integer, the below flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICCEN, CCCEN, RSTTYP, DTDSEL accorind to the command_index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
    set MSBSEL bit;
    if (finite block number) {
        set BCEN bit;
        if (auto12 command is to use) set AC12EN bit;
    }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function `wait_for_response` is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the Standby State, no response to the Host when CMD2 is sent. The Host Driver will deal with "fake" errors like this with caution.

59.5.2 Card Identification Mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for the MMC cards.

59.5.2.1 Card Detect

See the figure below for a flow diagram showing the detection of MMC, SD and SDIO cards using the uSDHC.

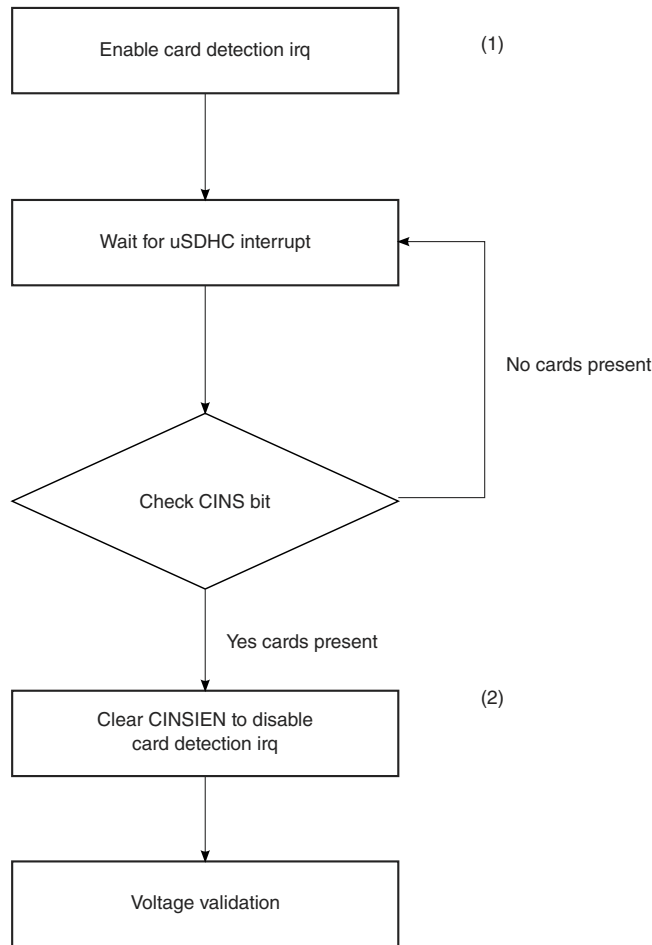

Figure 59-18. Flow Diagram for Card Detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

59.5.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) which is driven by POR (Power On Reset)

- Software reset (Host Only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the Host Controller, respectively
- Card reset (Card Only). The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the Idle State regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both the uSDHC and the card.

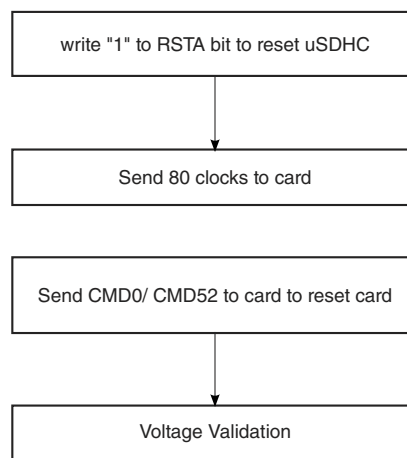

Figure 59-19. Flow Chart for Reset of the uSDHC and SD I/O Card

```

software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set_DTOCV and SDCLKFS bit fields to get the CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
  
```

59.5.2.3 Voltage Validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for Vdd are defined in the Operation Conditions Register (OCR) and may not cover the whole range.

Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer Vdd conditions. This means if the host and card have non-common Vdd ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory) and IO_Send_Op_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host. This is accomplished by the host sending the desired Vdd voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive State. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive State. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```

voltage_validation(voltage_range_argument)
{
    label the card as UNKNOWN;
    send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
    operation voltage, command argument is zero
    if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
        if (0 < number of IO functions) {
            label the card as SDIO;
            IORDY = 0;
            while (!(IORDY in IO OCR response)) { // set voltage range for each IO
                function
                    send_command(IO_SEND_OP_COND, <voltage range>, <other
parameter>);
                    wait_for_response(IO_SEND_OP_COND);
            } // end of while ...
        } // end of if (0 < ...
        if (memory part is present inside SDIO card) Label the card as SDCCombo; // this is
an
SD-Combo card
    } // end of if (RESP_TIMEOUT ...
    if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
    send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
    if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
        send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage
range
        for memory part or SD card
            wait_for_response(SD_APP_OP_COND); // voltage range is set
            if (Card type is UNKNOWN) label the card as SD;
            return; //
    } // end of if (no error ...
    else if (errors other than time-out occur) { // command/response pair is corrupted
        deal with it by program specific manner;
    } // of else if (response time-out
    else { // CMD55 is refuse, it must be MMC card if (card is already labelled as SDCCombo)
    { //
change label

```

```
        re-label the card as SDIO;
        ignore the error or report it;
        return; // card is identified as SDIO card
    } // of if (card is ...
    send_command(SEND_OP_COND, <voltage range>, <...>);
    if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
either
        label the card as UNKNOWN;
        return;
    } // of if (RESP_TIMEOUT ...
} // of else
}
```

59.5.2.4 Card Registry

Card registry for the MMC and SD/SDIO/SD Combo cards are different. For the SD Card, the Identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the Card spec). At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions.

The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the Inactive State. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready State), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification State.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. Once the RCA is received, the card changes its state to the Standby State. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive State. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards

(the cards in Ready State) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Since the CID is unique for each card, only one card can be successfully send its full CID to the host. This card then goes into the Identification State. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received the card state changes to the Stand-by State, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```

card_registry()
{
do { // decide RCA for each card until response time-out
    if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
        send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
        retrieve RCA from response;
    } // end if (card is labelled as SDCombo ...
else if (card is labelled as SD) { // for SD card
    send_command(ALL_SEND_CID, <...>);
    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
    send_command(SET_RELATIVE_ADDR, <...>);
    retrieve RCA from response;
} // else if (card is labelled as SD ...
else if (card is labelled as MMC) {
    send_command(ALL_SEND_CID, <...>);
    rca = 0x1; // arbitrarily set RCA, 1 here for example
    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
        } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}

```

59.5.3 Card Access

Information about Block Write, Block Read, Suspend Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

59.5.3.1 Block Write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

59.5.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the DATA line. The transferred data will be discarded and not written, and all further transmitted blocks (in multiple block write mode) will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DATA line without interrupting the write operation. When re-selecting the card, it will reactivate the busy indication by pulling DATA to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:

- For SD/MMC cards, use SET_BLOCKLEN (CMD16)
 - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
 4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
 5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
 6. Wait for the Transfer Complete interrupt.
 7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

59.5.3.1.2 DDR Write

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described as below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

59.5.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the Host Driver, the Driver can set the Stop At Block Gap Request(SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Like in the flow described in [Normal Write](#), the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
 - For SD/MMC, use SET_BLOCKLEN (CMD16)
 - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The Driver shall read the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card. This is because when such a command is sent, the uSDHC thinks the System will switch to another function on the SDIO card, and flush the data buffer. The uSDHC takes the Resume Command as a normal command with data transfer, and it is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to

send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC will automatically send a CMD12 to mark the end of the multi-block transfer.

59.5.3.2 Block Read

Information about Normal Read, DDR Read, Read with Pause, and DLL (Delay Line) in Read Path are detailed in the sections below.

59.5.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
 - For SD/MMC, use SET_BLOCKLEN (CMD16)
 - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

59.5.3.2.2 DDR Read

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

59.5.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks.

Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the uSDHC will not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit once the Read Wait capability of the SDIO card is recognized.

Like in the flow described in [Normal Read](#), the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
 - For SD/MMC, use SET_BLOCKLEN (CMD16)
 - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)

5. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
6. Set the uSDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the uSDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. No matter if the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the uSDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC will automatically send the CMD12 to mark the end of multi-block transfer.

59.5.3.2.4 DLL (Delay Line) in Read Path

The DLL(Delay Line) is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage and temperature (PVT).

The reasons why the DLL is needed for uSDHC are 1.) the path of read data traveling from card to host varies. 2.) in SD/MMC DDR mode the minimum input setup and hold time are both at 2.5 ns. The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in override mode. The override value set is the number of delay cells. In override mode, there is no need to set the `DLL_enable`. Another DLL mode is target value mode. In this mode, the DLL will automatically adjust the number of delay cells according to target value set by user and PVT changes. Be aware that target value is in units of 1/32 of the clock reference period. If the `card_clk` is 100Mhz, then the reference clock period is 10ns, setting target vaule of 16 means $5\text{ns} = (16/32) * 10\text{ns}$. Software can disable automatic update by setting `dll_gate_update` bit. Please refer to [Figure 59-20](#).

Since the user may change the frequency of the `card_clk` from time to time by changing `SDCLKFS[7:0]/DVS[3:0]`, the software must adjust the delay value to ensure it works correctly when the reference clock (`card_clk`) is changed. The following is the correct flow, which should be ignored if `DLL_CTRL_ENABLE` is not set.

Step 1: Set `DLL_CTRL_RESET` bit

Step 2: Configure the `SDCLKFS[7:0]` and `DVS[3:0]`

Step 3: Wait until `SDSTB` is asserted

Step 4: clear `DLL_CTRL_RESET` bit

Step 5: Wait until both `DLL_STS_SLV_LOCK` and `DLL_STS_REF_LOCK` are asserted

Step 6: set `DLL_CTRL_SLV_FORCE_UPD`

Step 7: clear `DLL_CTRL_SLV_FORCE_UPD`

NOTE:Software should make sure the `DLL_CTRL_SLV_FORCE_UPD` is lasted for at least one `card_clk`. So software may need to add some delay between step6 and step7.

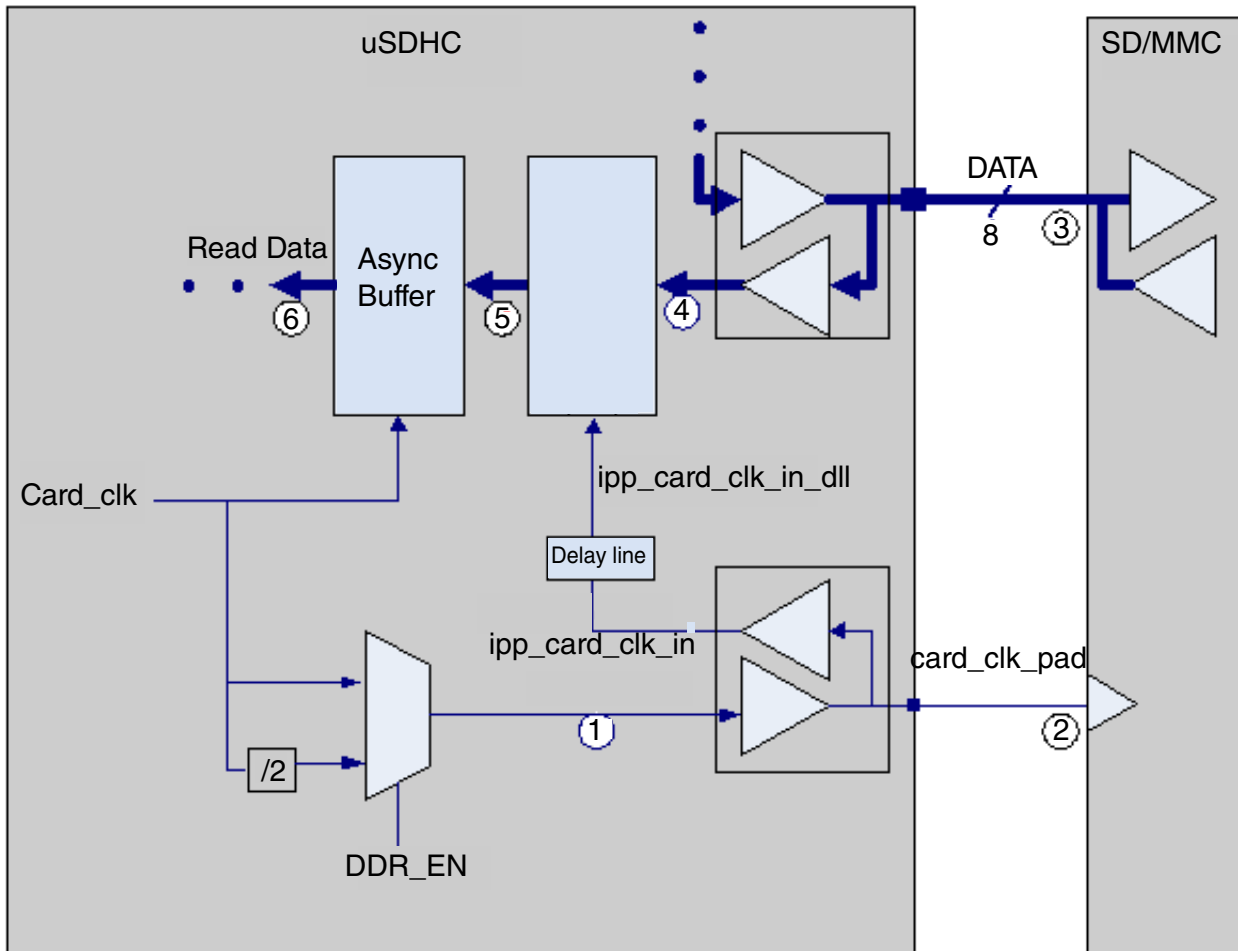

Figure 59-20. DLL(Delay Line) in Read Path

59.5.3.3 Suspend Resume

The uSDHC supports the Suspend Resume operations of SDIO cards, although slightly differently than the suggested implementation of Suspend in the SDIO card specification.

59.5.3.3.1 Suspend

After setting the SABGREQ bit, the Host Driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC does not monitor the content of the response, so it doesn't know if the Suspend command succeeded or not. Accordingly, it doesn't de-assert Read Wait for read pause. To solve this problem, the Driver shall not mark the Suspend command as a "Suspend", (i.e. setting the CMDTYP bits to 01). Instead, the Driver shall send this command as if it were a normal command, and only

when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform the uSDHC that the current transfer is suspended. As shown in the following sequence for Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so the uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

59.5.3.3.2 Resume

To resume the data transfer, a Resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation above.
2. Send the Resume command. In the Transfer Type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer will be resumed.

59.5.3.4 ADMA Usage

To use the ADMA in a data transfer, the Host Driver must prepare the correct descriptor chain prior to sending the read/write command.

The steps to prepare the correct descriptor chain are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4kB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.

4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

59.5.3.5 Transfer Error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 Errors are detailed in the sections below.

59.5.3.5.1 CRC Error

It is possible at the end of a block transfer, that a write CRC status error or read CRC error occurs. For this type of error the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one.

For a multi-block transfer, the Host Driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, the uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 will be sent by the uSDHC. In this case, the Driver shall re-send or re-obtain the last block with a single block transfer.

59.5.3.5.2 Internal DMA Error

During the data transfer with internal Simple DMA, if the DMA engine encounters some error on the AHB bus, the DMA operation is aborted and DMA Error interrupt is sent to the Host System. When acknowledged by such an interrupt, the Driver shall calculate the start address of data block in which the error occurs.

The start address can be calculated by either:

1. Reading the DMA System Address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the

next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.

2. Reading the BLKCNT field of the Block Attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register does not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and re-start the transfer from the corrupted block to recover from the error.

59.5.3.5.3 Transfer ADMA Error

There are 3 kinds of possible ADMA errors. The AHB transfer, invalid descriptor, and data-length mismatch errors. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set.

For acknowledging the status, the Host Driver should recover the error as shown below and re-transfer from the place of interruption.

1. AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and re-create the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
3. Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

59.5.3.5.4 Auto CMD12 Error

After the last block of the multi block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, the uSDHC automatically sends a CMD12 to the card to stop the transfer.

When errors with this command occur, it is recommended to the Driver to deal with the situations in the following manner:

1. Auto CMD12 response time-out. It is not certain whether the command is accepted by the card or not. The Driver should clear the Auto CMD12 error status bits and re-send the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error. Since card responds to the CMD12, the card will abort the transfer. The Driver may ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The command is not sent, so the Driver shall send a CMD12 manually.

59.5.3.6 Card Interrupt

The external cards can inform the Host Controller by means of some special signals. For the SDIO card, it can be the low level on the DATA1 line during some special period. The uSDHC only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the uSDHC, and the Host System is informed by the uSDHC asserting the uSDHC interrupt line, the interrupt service from the Host Driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by written. Refer to [Card Interrupt Handling](#) for the card interrupt handling flow.

59.5.4 Switch Function

A switch command must be issued by the Host Driver to enable new features added to the SD/MMC spec. SD/MMC cards can transfer data at bus widths other than 1-bit. Different speed mode are also defined. To enable these features, a switch command shall be issued by the Host Driver.

For SDIO cards, the high speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards, the high speed mode/HS200 are queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit and DDR8-bit width of the MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

59.5.4.1 Query, Enable and Disable SDIO High Speed Mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

59.5.4.2 Query, Enable and Disable SD High Speed Mode/SDR50/SDR104/DDR50

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFF0 and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz for high speed mode, 100Mhz for SDR50, 200Mhz for SDR104, 50Mhz for
DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
```

```

if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}

```

59.5.4.3 Query, Enable and Disable MMC High Speed Mode

```

enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}

```

59.5.4.4 Set MMC Bus Width

```

change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-
bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}

```

59.5.5 ADMA Operation

Code for ADMA1 Operation and ADMA2 Operation can be found here.

59.5.5.1 ADMA1 Operation

```

Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}

```

59.5.5.2 ADMA2 Operation

```

Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}

```

59.5.6 Fast Boot Operation

59.5.6.1 Normal fast boot flow

1. Software must configure `init_active` bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software must configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode or not. If the data will be sent through DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set DTW (data transfer width). If in DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, `CMDINX`, `CMDTYP`, `RSPTYP`, `CICEN`, `CCEN`, `AC12EN`, `BCEN` and `DMAEN` are kept at the default value. `DPSEL` bit is set to 1, `DTDSEL` is set to 1, `MSBSEL` is set to 1.
7. `DMAEN` should be configured as 0 in polling mode. And if `BCEN` is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, `DDR_EN` needs to be set to 1.
8. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt will be triggered, and software must configure MMC Boot Register to bit 6 to 0 to disable boot. This makes `CMD` high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This will make `CMD` line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
10. Reset the host and then can begin the normal process.

59.5.6.2 Alternative fast boot flow

1. Software needs to configure `init_active` bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the DTW (data transfer width). If in ddr fast boot mode, DTW only can be configure to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with 0xFFFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. Note DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
7. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host will send out the interrupt and software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process..
8. If there is no time out, software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the MMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. Reset the host and then begin the normal process.

59.5.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during MMC fast boot.

In fast boot, the host can use ADMA2 (Advanced DMA2) with two destinations.

The detail flow is described below:

1. Software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that that the host will stop at the block gap when the uSDHC controller gets VALUE1 blocks from the device. Also configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hfff).
4. Software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. Software need to set at least three pairs ADMA2 descriptor in boot memory (ie, in IRAM, at least 6 word). The first pair descriptor define the start address (ie, IRAM) and data length (ie, 512byte*VALUE1) of first part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writeable), data length is suggest to set 1~2word (record as VALUE2). Note: the second couple desc also transfer useful data even at lease 1 word. Because our ADMA2 can't support 0 data_length data transfer descriptor.
7. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFFFA in alternative fast boot, and don't need set in normal fast boot.
8. Software needs to configure Transfer Type Register to start the boot process . CMDINX, CMDTYP, RSPTYP, C ICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. DMAEN is configured as 1 in DMA mode. And if BCEN is configured as 1, better to configure blk no in Block Attributes Register to the max value. And if in ddr fast boot mode, DDR_EN need to be set to 1.
9. When the step 8 is configured, boot process will begin, the first VALUE1 block number data has transfer. Software need to polling TC bit (bit1 in Interrupt Status Register) to determine first transfer is end. Also software need to polling BGE bit (bit2 in Interrupt Status Register) to determine if first transfer stop at block gap.

10. When TC, BGE bit is 1, . SW can analyzes the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of boot code(VALUE3 the remain boot code block). Remeber set the last descriptor with END.
11. Software needs to configure MMC Boot Register (offset 0xc4) again. Set bit 6 to 1(enable boot); and bit 5 to 0(normal fast boot), to 1(alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 for enable automatically stop at block gap feature. Also configure bit31-bit16 to set the $(BLK_CNT - (VALUE1+1+VALUE3))$, that host will stop at block gap when *the uSDHC controller gets (VALUE1+1+VALUE3) blocks from device totally include the blocks received in step 9*. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequence. Please note, Software doesn't need to configure the *BLK_CNT* again, because it's counted down automatically by the uSDHC controller.
12. Software needs to clear TC and BGE bit. And software needs to clear SABGREQ(bit 16 in Protocol control register), and set CREQ(bit17 Protocol control register) to 1 to resume the data transfer. Host will transfer the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. Software need to polling BGE bit to determine if the fast boot is over.

Note:

1. When ADMA boot flow is started, for uSDHC, it is like a normal ADMA read operation. So setting ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2 word data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

59.6 Commands for MMC/SD/SDIO

A table containing the list of commands for the MMC/SD/SDIO cards can be found here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. broadcast commands (bc), no response.
2. broadcast commands with response (bcr), response from all cards simultaneously.
3. addressed (point-to-point) commands (ac), no data transfer on the DATA.
4. addressed (point-to-point) data transfer commands (adtc).

Response: a response is a token which is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 59-3. Commands for MMC/SD/SDIO Cards

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3 ¹	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_AD DR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD6 ²	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6 ³	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.

Table continues on the next page...

Table 59-3. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	Reserved				
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISSION follows.
CMD21-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation

Table continues on the next page...

Table 59-3. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
					after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This

Table continues on the next page...

Table 59-3. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
					command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62-63	Reserved				
ACMD6 ⁴	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.

Table continues on the next page...

Table 59-3. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
ACMD13 ⁴	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22 ⁴	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23 ⁴	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).
ACMD41 ⁴	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42 ⁴	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.
ACMD51 ⁴	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in [Table 2](#).
4. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The Access Bits for the EXT_CSD Access Modes are shown below.

Table 59-4. EXT_CSD Access Modes

Bits	Access Name	Operation
00	Command Set	The command set is changed according to the Cmd Set field of the argument
01	Set Bits	The bits in the pointed byte are set, according to the 1 bits in the Value field.
10	Clear Bits	The bits in the pointed byte are cleared, according to the 1 bits in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

59.7 Software Restrictions

59.7.1 Initialization Active

The driver cannot set INITA bit in System Control register when any of the command line or data lines is active, so the driver must ensure both CDIHB and CIHB bits are cleared.

59.7.2 Software Polling Procedure

For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block.

For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

59.7.3 Suspend Operation

In order to suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such 'suspend' command, uSDHC will regard the current transfer is aborted and change BLKCNT register to its original value, instead of keeping the remained number of blocks.

59.7.4 Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

59.7.5 (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register will always update itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

59.7.6 Data Port Access

Data Port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the Data Port by CPU; or during a CPU read operation, it is also prohibited to write any data to the Data Port, by either CPU or external DMA. Otherwise the data would be corrupted inside the uSDHC buffer.

59.7.7 Change Clock Frequency

uSDHC does not automatically gate off the card clock when the Host Driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing clock divisor value(SDCLKFS or DVS in System Control Register) or setting RSTA bit.

Also before changing the clock divisor value, Host Driver should make sure the SDSTB bit is high.

59.7.8 Multi-block Read

For pre-defined multi-block read operation, i.e., the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode.

In this case, the card may not respond to this extra abort command and uSDHC will get Response Timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

59.8 uSDHC Memory Map/Register Definition

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map for the uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

uSDHC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
219_0000	DMA System Address (uSDHC1_DS_ADDR)	32	R/W	0000_0000h	59.8.1/3798
219_0004	Block Attributes (uSDHC1_BLK_ATT)	32	R/W	0000_0000h	59.8.2/3799

59.8.1 DMA System Address (uSDHCx_DS_ADDR)

This register contains the physical system memory address used for DMA transfers.

Address: Base address + 0h offset

uSDHCx_DS_ADDR field descriptions

Field	Description
DS_ADDR	<p>DMA System Address / Argument 2</p> <p>When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both 32-bit and 64-bit addressing. This register is used only for Argument2 and SDMA may use Auto CMD23.</p> <p>1. SDMA System Address</p> <p>Since the address must be word (4 bytes) aligned, the least 2 bits are reserved, always 0. When the uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operation during transfers may return an invalid value. The Host Driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register.</p> <p>This register is protected during a data transfer. When data lines are active, write to this register is ignored. The Host driver shall wait, until the DLA bit in the Present State register is cleared, before writing to this register.</p> <p>The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, uSDHC will automatically change SEQ burst type to NSEQ.</p> <p>Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions.</p> <p>2. Argument 2</p> <p>This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23.</p> <p>If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.</p>

59.8.2 Block Attributes (uSDHCx_BLK_ATT)

This register is used to configure the number of data blocks and the number of bytes in each block.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BLKCNT																0	BLKSIZE[12:0]														
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

uSDHCx_BLK_ATT field descriptions

Field	Description
31–16 BLKCNT	Blocks Count For Current Transfer:

Table continues on the next page...

uSDHCx_BLK_ATT field descriptions (continued)

Field	Description
	<p>This register is enabled when the Block Count Enable bit in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The Host Driver shall set this register to a value between 1 and the maximum block count. The uSDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred.</p> <p>This register should be accessed only when no transaction is executing (i.e. after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored.</p> <p>When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when Suspend command is sent out, uSDHC will regard the current transfer is aborted and change BLKCNT register back to its original value instead of keeping the dynamical indicator of remained block count.</p> <p>When restoring transfer content prior to issuing a Resume command, the Host Driver shall restore the previously saved block count.</p> <p>NOTE: Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL bit is indicating a single block transfer, the read value of BLKCNT is always 1.</p> <p>FFFF 65535 blocks 0002 2 blocks 0001 1 block 0000 Stop Count</p>
15–13 Reserved	This read-only field is reserved and always has the value 0.
BLKSIZE[12:0]	<p>Transfer Block Size:</p> <p>This register specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations will be ignored.</p> <p>1000 4096 Bytes 800 2048 Bytes 200 512 Bytes 1FF 511 Bytes 004 4 Bytes 003 3 Bytes 002 2 Bytes 001 1 Byte 000 No data transfer</p>

59.8.3 Command Argument (uSDHCx_CMD_ARG)

This register contains the SD / MMC Command Argument.

Address: Base address + 8h offset

**uSDHCx_CMD_ARG field descriptions**

Field	Description
CMDARG[31:0]	Command Argument The SD / MMC Command Argument is specified as bits 39-8 of the Command Format in the SD or MMC Specification. This register is write protected when the Command Inhibit (CMD) bit in the Present State register is set.

59.8.4 Command Transfer Type (uSDHCx_CMD_XFR_TYP)

This register is used to control the operation of data transfers. The Host Driver shall set this register before issuing a command followed by a data transfer, or before issuing a Resume command. To prevent data loss, the uSDHC prevents writing to the bits, that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.

The Host Driver shall check the Command Inhibit DAT bit (CDIHB) and the Command Inhibit CMD bit (CIHB) in the Present State register before writing to this register. When the CDIHB bit in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC will ignore the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is '1'), otherwise uSDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, i.e., response time-out, uSDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver should issue the command again to re-try the transfer. It is also possible that for some reason the card responds the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 59-5. Transfer Type Register Setting for Various Transfer Types

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, in regards to the Response Type bits as well as the name of the response type.

Table 59-6. Relationship Between Parameters and the Name of the Response Type

Response Type	Index Check Enable	CRC Check Enable	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3,R4
10	1	1	R1,R5,R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to specify that the uSDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command shall be used with R5b.
- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

Address: Base address + Ch offset

uSDHCx_CMD_XFR_TYP field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value 0.
29–24 CMDINX[5:0]	Command Index These bits shall be set to the command number that is specified in bits 45-40 of the Command-Format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23–22 CMDTYP[1:0]	Command Type There are three types of special commands: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. <ul style="list-style-type: none"> Suspend Command: If the Suspend command succeeds, the uSDHC shall assume that the card bus has been released and that it is possible to issue the next command which uses the DATA line. Since the uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the Host Driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform the uSDHC that a Suspend command was successfully issued. Refer to Suspend Resume for more details. After the end bit of command is sent, the uSDHC de-asserts Read Wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the uSDHC will maintain its current state, and the Host Driver shall restart the transfer by setting the Continue Request bit in the Protocol Control register. Resume Command: The Host Driver re-starts the data transfer by restoring the registers saved before sending the Suspend Command and then sends the Resume Command. The uSDHC will check for a pending busy state before starting write transfers. Abort Command: If this command is set when executing a read transfer, the uSDHC will stop reads to the buffer. If this command is set when executing a write transfer, the uSDHC will stop driving the DATA line. After issuing the Abort command, the Host Driver should issue a software reset (Abort Transaction). 11 Abort CMD12, CMD52 for writing I/O Abort in CCCR 10 Resume CMD52 for writing Function Select in CCCR 01 Suspend CMD52 for writing Bus Suspend in CCCR 00 Normal Other commands
21 DPSEL	Data Present Select This bit is set to 1 to indicate that data is present and shall be transferred using the DATA line. It is set to 0 for the following: <ul style="list-style-type: none"> Commands using only the CMD line (e.g. CMD52). Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b e.g. CMD38)

Table continues on the next page...

uSDHCx_CMD_XFR_TYP field descriptions (continued)

Field	Description
	<p>NOTE: In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. When the Write Protect switch is on, (i.e. the WPSPL bit is active as '0'), any command with a write operation will be ignored. That is to say, when this bit is set, while the DTSEL bit is 0, writes to the register Transfer Type are ignored.</p> <p>1 Data Present 0 No Data Present</p>
20 CICEN	<p>Command Index Check Enable</p> <p>If this bit is set to 1, the uSDHC will check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked.</p> <p>1 Enable 0 Disable</p>
19 CCEN	<p>Command CRC Check Enable</p> <p>If this bit is set to 1, the uSDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. (Refer to RSPTYP[1:0] and Command Transfer Type (uSDHC_CMD_XFR_TYP) .)</p> <p>1 Enable 0 Disable</p>

Field	Description
	Refer to Command Response3 (uSDHC_CMD_RSP3) for the mapping of command responses from the SD Bus to this register for each response type.

59.8.8 Command Response3 (uSDHCx_CMD_RSP3)

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD Bus to Command Response registers for each response type. In the table, R[] refers to a bit range within the response data as transmitted on the SD Bus.

Table 59-7. Response Bit Definition for Each Response Type

Response Type	Meaning of Response	Response Field	Response Register
R1,R1b (normal response)	Card Status	R[39:8]	CMDRSP0
R1b (Auto CMD12 response)	Card Status for Auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (Publish RCA)	New Published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the uSDHC only stores part of the response data in the Command Response registers. This enables the Host Driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by the uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit

range for the CRC check depends on the response length. If the response length is 48, the uSDHC will check R[47:1], and if the response length is 136 the uSDHC will check R[119:1].

Since the uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, the uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows the uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When the uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

Address: Base address + 1Ch offset

uSDHCx_CMD_RSP3 field descriptions

Field	Description
CMDRSP3[31:0]	Command Response 3 Refer to Command Response3 (uSDHC_CMD_RSP3) for the mapping of command responses from the SD Bus to this register for each response type.

59.8.9 Data Buffer Access Port (uSDHCx_DATA_BUFF_ACC_PORT)

This is a 32-bit data port register used to access the internal buffer.

Address: Base address + 20h offset

uSDHCx_DATA_BUFF_ACC_PORT field descriptions

Field	Description
DATCONT[31:0]	Data Content The Buffer Data Port register is for 32-bit data access by the ARM platform or the external DMA. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s.

59.8.10 Present State (uSDHCx_PRES_STATE)

The Host Driver can get status of the uSDHC from this 32-bit read only register.

- The Host Driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands shall be issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.
- Note: the reset value of Present State Register depend on testbench connectivity.

Address: Base address + 24h offset

uSDHCx_PRES_STATE field descriptions

Field	Description
31–24 DLSL[7:0]	<p>DATA[7:0] Line Signal Level</p> <p>This status is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this bit field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up.</p> <p>DATA7 Data 7 line signal level DATA6 Data 6 line signal level DATA5 Data 5 line signal level DATA4 Data 4 line signal level DATA3 Data 3 line signal level DATA2 Data 2 line signal level DATA1 Data 1 line signal level DATA0 Data 0 line signal level</p>
23 CLSL	<p>CMD Line Signal Level</p> <p>This status is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this bit after reset is 1'b1, when the command line is pulled up.</p>
22–20 Reserved	This read-only field is reserved and always has the value 0.
19 WPSPL	<p>Write Protect Switch Pin Level</p> <p>The Write Protect Switch is supported for memory and combo cards. This bit reflects the inverted value of the WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this bit is high and write is enabled.</p> <p>1 Write enabled (WP = 0) 0 Write protected (WP = 1)</p>
18 CDPL	<p>Card Detect Pin Level</p> <p>This bit reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing since it must be debounced by software. A software reset does not effect this bit. A write to the Force Event Register does not effect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the CD_B pin (i.e. when a card is inserted in the socket, it is 0 on the CD_B input, and consequently the CDPL reads 1.)</p> <p>1 Card present (CD_B = 0) 0 No card present (CD_B = 1)</p>
17 Reserved	This read-only field is reserved and always has the value 0.
16 CINST	<p>Card Inserted</p> <p>This bit indicates whether a card has been inserted. The uSDHC debounces this signal so that the Host Driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not effect this bit.</p> <p>The Software Reset For All in the System Control register does not effect this bit. A software reset does not effect this bit.</p>

Field	Description
	<ul style="list-style-type: none"> After the end bit of the read command. When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. <p>A Transfer Complete interrupt is generated when this bit changes to 0. This bit is cleared for either of the following conditions:</p> <ul style="list-style-type: none"> When the last data block as specified by block length is transferred to the System, i.e. all data are read away from uSDHC internal buffer. When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1. <p>1 Transferring data 0 No valid data</p>
8 WTA	<p>Write Transfer Active</p> <p>This status bit indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the uSDHC.</p> <p>This bit is set in either of the following cases:</p> <ul style="list-style-type: none"> After the end bit of the write command. When writing 1 to the Continue Request bit in the Protocol Control register to restart a write transfer. <p>This bit is cleared in either of the following cases:</p> <ul style="list-style-type: none"> After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple). After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request. <p>During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining when to issue commands during Write Busy state.</p> <p>1 Transferring data 0 No valid data</p>
7 SDOFF	<p>SD Clock Gated Off Internally</p> <p>This status bit indicates that the SD Clock is internally gated off, because of buffer over / under-run or read pause without read wait assertion, or the driver set FRC_SDCLK_ON bit is 0 to stop the SD clock in idle status. Set IPG_PERCLK_SOFT_EN and CARD_CLK_SOFT_EN to 0 also gate off SD clock. This bit is for the Host Driver to debug data transaction on the SD bus.</p> <p>1 SD Clock is gated off. 0 SD Clock is active.</p>
6 PEROFF	<p>IPG_PERCLK Gated Off Internally</p> <p>This status bit indicates that the IPG_PERCLK is internally gated off. This bit is for the Host Driver to debug transaction on the SD bus. When IPG_CLK_SOFT_EN is cleared, IPG_PERCLK will be gated off, otherwise IPG_PERCLK will be always active.</p> <p>1 IPG_PERCLK is gated off. 0 IPG_PERCLK is active.</p>
5 HCKOFF	<p>HCLK Gated Off Internally</p>

Table continues on the next page...

uSDHCx_PRES_STATE field descriptions (continued)

Field	Description
	<p>This status bit indicates that the HCLK is internally gated off. This bit is for the Host Driver to debug during a data transfer.</p> <p>1 HCLK is gated off. 0 HCLK is active.</p>
<p>4 IPGOFF</p>	<p>IPG_CLK Gated Off Internally</p> <p>This status bit indicates that the ipg_clk is internally gated off. This bit is for the Host Driver to debug.</p> <p>1 IPG_CLK is gated off. 0 IPG_CLK is active.</p>
<p>3 SDSTB</p>	<p>SD Clock Stable</p> <p>This status bit indicates that the internal card clock is stable. This bit is for the Host Driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON bit in System Control register to remove glitches on the card clock when the frequency is changing.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p>1 Clock is stable. 0 Clock is changing frequency and not stable.</p>
<p>2 DLA</p>	<p>Data Line Active</p> <p>This status bit indicates whether one of the DATA lines on the SD Bus is in use.</p> <p>In the case of read transactions:</p> <p>This status indicates if a read transfer is executing on the SD Bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register.</p> <p>This bit will be set in either of the following cases:</p> <ul style="list-style-type: none"> • After the end bit of the read command. • When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. <p>This bit will be cleared in either of the following cases:</p> <p>(1) When the end bit of the last data block is sent from the SD Bus to the uSDHC. (2) When the Read Wait state is stopped by a Suspend command and the DATA2 line is released.</p> <p>The uSDHC will wait at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), the uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait in order to use the suspend / resume function. This bit will remain 1 during Read Wait.</p> <p>In the case of write transactions:</p> <p>This status indicates that a write transfer is executing on the SD Bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register.</p> <p>This bit will be set in either of the following cases:</p> <ul style="list-style-type: none"> • After the end bit of the write command. • When writing to 1 to the Continue Request bit in the Protocol Control register to continue a write transfer. <p>This bit will be cleared in either of the following cases:</p>

Table continues on the next page...

uSDHCx_PRES_STATE field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> When the SD card releases Write Busy of the last data block, the uSDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the uSDHC shall assume the card drive "Not Busy". When the SD card releases write busy, prior to waiting for write transfer, and as a result of a Stop At Block Gap Request. <p>In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DATA0 line is released.</p> <p>1 DATA Line Active 0 DATA Line Inactive</p>
1 CDIHB	<p>Command Inhibit (DATA)</p> <p>This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates that the uSDHC can issue the next SD / MMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register.</p> <p>NOTE: The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0.</p> <p>1 Cannot issue command which uses the DATA line 0 Can issue command which uses the DATA line</p>
0 CIHB	<p>Command Inhibit (CMD)</p> <p>If this status bit is 0, it indicates that the CMD line is not in use and the uSDHC can issue a SD / MMC Command using the CMD line.</p> <p>This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If the uSDHC cannot issue the command because of a command conflict error (Refer to Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this bit will remain 1 and the Command Complete is not set. The Status of issuing an Auto CMD12 does not show on this bit.</p> <p>1 Cannot issue command 0 Can issue command using only CMD line</p>

59.8.11 Protocol Control (uSDHCx_PROT_CTRL)

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the uSDHC issues a Suspend command or the SD card accepts the Suspend command.

1. If the Host Driver does not issue a Suspend command, the Continue Request shall be used to restart the transfer.
2. If the Host Driver issues a Suspend command and the SD card accepts it, a Resume command shall be used to restart the transfer.

3. If the Host Driver issues a Suspend command and the SD card does not accept it, the Continue Request shall be used to restart the transfer.

Any time Stop At Block Gap Request stops the data transfer, the Host Driver shall wait for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the Host Driver shall clear the Stop At Block Gap Request before or simultaneously.

uSDHCx_PROT_CTRL field descriptions

Field	Description
31 -	Reserved. Always write as 0
30 NON_EXACT_BLK_RD	Current block read is non-exact block read. It is only used for SDIO. 1 The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read. 0 The block read is exact block read. Host driver doesn't need to issue abort command to terminate this multi-block read.
29-27 BURST_LEN_EN	BURST length enable for INCR, INCR4 / INCR8 / INCR16, INCR4-WRAP / INCR8-WRAP / INCR16-WRAP This is used to enable / disable the burst length for the external AHB2AXI bridge. It is useful especially for INCR transfer because without burst length indicator, the AHB2AXI bridge does not know the burst length in advance. Without burst length indicator, AHB INCR transfers can only be converted to SINGLES on the AXI side. xx1 Burst length is enabled for INCR x1x Burst length is enabled for INCR4 / INCR8 / INCR16 1xx Burst length is enabled for INCR4-WRAP / INCR8-WRAP / INCR16-WRAP
26 WECRM	Wakeup Event Enable On SD Card Removal

Table continues on the next page...

uSDHCx_PROT_CTRL field descriptions (continued)

Field	Description
	<p>This bit enables a wakeup event, via a Card Removal, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Removal Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Removal Status and the uSDHC interrupt.</p> <p>1 Enable 0 Disable</p>
25 WECINS	<p>Wakeup Event Enable On SD Card Insertion</p> <p>This bit enables a wakeup event, via a Card Insertion, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Insertion Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Insertion Status and the uSDHC interrupt.</p> <p>1 Enable 0 Disable</p>
24 WECINT	<p>Wakeup Event Enable On Card Interrupt</p> <p>This bit enables a wakeup event, via a Card Interrupt, in the Interrupt Status register. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the Card Interrupt Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Interrupt Status and the uSDHC interrupt.</p> <p>1 Enable 0 Disable</p>
23–21 -	Reserved. Always write as 3'b100
20 RD_DONE_NO_8CLK	<p><i>Read done no 8 clock:</i></p> <p><i>According to the SD/MMC spec, for read data transaction, 8 clocks are needed after the end bit of the last data block. So, by default(RD_DONE_NO_8CLK=0), 8 clocks will be active after the end bit of the last read data transaction.</i></p> <p><i>However, this 8 clocks should not be active if user wants to use stop at block gap(include the auto stop at block gap in boot mode) feature for read and the RWCTL bit(bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid this 8 clocks. Otherwise, the device may send extra data to uSDHC while uSDHC ignores these data.</i></p> <p><i>In a summary, this bit should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.</i></p>
19 IABG	<p>Interrupt At Block Gap</p> <p>This bit is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0 to avoid an inadvertent interrupt. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card.</p> <p>1 Enabled 0 Disabled</p>
18 RWCTL	<p>Read Wait Control</p> <p>The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise the uSDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SDIO</p>

Table continues on the next page...

uSDHCx_PROT_CTRL field descriptions (continued)

Field	Description
	<p>card insertion, it shall set this bit according to the CCCR of the card. If the card does not support read wait, this bit shall never be set to 1, otherwise DATA line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the uSDHC will stop the SD Clock to pause reading operation.</p> <p>1 Enable Read Wait Control, and assert Read Wait without stopping SD Clock at block gap when SABGREQ bit is set 0 Disable Read Wait Control, and stop SD Clock at block gap when SABGREQ bit is set</p>
17 CREQ	<p>Continue Request</p> <p>This bit is used to restart a transaction which was stopped using the Stop At Block Gap Request. When a Suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit to 1 to restart the transfer.</p> <p>The uSDHC automatically clears this bit, therefore it is not necessary for the Host Driver to set this bit to 0. If both Stop At Block Gap Request and this bit are 1, the continue request is ignored.</p> <p>1 Restart 0 No effect</p>
16 SABGREQ	<p>Stop At Block Gap Request</p> <p>This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the Transfer Complete is set to 1, indicating a transfer completion, the Host Driver shall leave this bit set to 1. Clearing both the Stop At Block Gap Request and Continue Request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC will honor the Stop At Block Gap Request for write transfers, but for read transfers it requires that the SDIO card support Read Wait. Therefore, the Host Driver shall not set this bit during read transfers unless the SDIO card supports Read Wait and has set the Read Wait Control to 1, otherwise the uSDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the Host Driver writes data to the Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to the Data Port register after a block is sent. Once this bit is set, the Host Driver shall not clear this bit before the Transfer Complete bit in Interrupt Status Register is set, otherwise the uSDHCs behavior is undefined.</p> <p>This bit effects Read Transfer Active, Write Transfer Active, DATA Line Active and Command Inhibit (DATA) in the Present State register.</p> <p>1 Stop 0 Transfer</p>
15–10 Reserved	<p>This read-only field is reserved and always has the value 0.</p>
9–8 DMASEL	<p>DMA Select</p> <p>This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation.</p> <p>00 No DMA or Simple DMA is selected 01 ADMA1 is selected 10 ADMA2 is selected 11 reserved</p>
7 CDSS	<p>Card Detect Signal Selection</p> <p>This bit selects the source for the card detection.</p>

Table continues on the next page...

uSDHCx_PROT_CTRL field descriptions (continued)

Field	Description
	1 Card Detection Test Level is selected (for test purpose). 0 Card Detection Level is selected (for normal purpose).
6 CDTL	Card Detect Test Level This bit is enabled while the Card Detection Signal Selection is set to 1 and it indicates card insertion. 1 Card Detect Test Level is 1, card inserted 0 Card Detect Test Level is 0, no card inserted
5-4 EMODE	Endian Mode The uSDHC supports all three endian modes in data transfer. Refer to Data Buffer for more details. 00 Big Endian Mode 01 Half Word Big Endian Mode 10 Little Endian Mode 11 Reserved
3 D3CD	DATA3 as Card Detection Pin If this bit is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 may set the card into the SPI mode, which the uSDHC does not support. 1 DATA3 as Card Detection Pin 0 DATA3 does not monitor Card Insertion
2-1 DTW[1:0]	Data Transfer Width This bit selects the data width of the SD bus for a data transfer. The Host Driver shall set it to match the data width of the card. Possible Data transfer Width is 1-bit, 4-bits or 8-bits. 10 8-bit mode 01 4-bit mode 00 1-bit mode 11 Reserved
0 LCTL	LED Control This bit, fully controlled by the Host Driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this bit can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the bit once before the first command is sufficient: it is not necessary to reset the bit between commands. 1 LED on 0 LED off

59.8.12 System Control (uSDHCx_SYS_CTRL)

uSDHCx_SYS_CTRL field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28 RSTT	Reset Tuning When set this bit to 1, it will reset tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning bit in AUTOCMD12_ERR_STATUS will also set this bit to 1 to reset tuning circuit
27 INITA	Initialization Active When this bit is set, 80 SD-Clocks are sent to the card. After the 80 clocks are sent, this bit is self cleared. This bit is very useful during the card power-up period when 74 SD-Clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the CIHB and CDIHB bits in the Present State Register are set, writing 1 to this bit is ignored (i.e. when command line or data lines are active, write to this bit is not allowed). On the otherhand, when this bit is set, i.e., during intialization active period, it is allowed to issue command, and the command bit stream will appear on the CMD pad after all 80 clock cycles are done. So when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs send 80 cycles to the card and does not want to wait till this bit is self cleared.
26 RSTD	Software Reset For DATA Line

This register field selects the divide value of the second divisor stage.</p> <p><i>In Single Data Rate mode(DDR_EN bit of MIXERCTRL is '0')</i></p> <p>Only the following settings are allowed:</p> <p>80h) Base clock divided by 256 40h) Base clock divided by 128 20h) Base clock divided by 64 10h) Base clock divided by 32 08h) Base clock divided by 16 04h) Base clock divided by 8 02h) Base clock divided by 4 01h) Base clock divided by 2 00h) Base clock divided by 1</p> <p><i>While in Dual Data Rate mode(DDR_EN bit of MIXERCTRL is '1')</i></p> <p>Only the following settings are allowed:</p> <p>80h) Base clock divided by 512 40h) Base clock divided by 256 20h) Base clock divided by 128 10h) Base clock divided by 64 08h) Base clock divided by 32 04h) Base clock divided by 16 02h) Base clock divided by 8 01h) Base clock divided by 4 00h) Base clock divided by 2</p> <p><i>When S/W changes the DDR_EN bit, SDCLKFS may need to be changed also!</i></p> <p>In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD Clock.</p>

Table continues on the next page...

uSDHCx_SYS_CTRL field descriptions (continued)

Field	Description										
	<p>Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits.</p> <p>The frequency of SDCLK is set by the following formula:</p> $\text{Clock Frequency} = (\text{Base Clock}) / (\text{prescaler} \times \text{divisor})$ <p>For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz.</p> <p>The reset value of this bit field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD Clock after reset is 375 kHz.</p> <p>According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD Clock frequency is 50 MHz and shall never exceed this limit.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p><i>If setting SDCLKFS and DVS can generate same clock frequency,(For example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.) SDCLKFS is highly recommended.</i></p>										
7-4 DVS[3:0]	<p>Divisor</p> <p>This register is used to select the frequency of the SDCLK pin. This register field selects the divide value of the first divisor stage.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p>The setting are as following:</p> <table> <tr> <td>0000</td> <td>Divide-by-1</td> </tr> <tr> <td>0001</td> <td>Divide-by-2</td> </tr> <tr> <td>.....</td> <td></td> </tr> <tr> <td>1110</td> <td>Divide-by-15</td> </tr> <tr> <td>1111</td> <td>Divide-by-16</td> </tr> </table>	0000	Divide-by-1	0001	Divide-by-2		1110	Divide-by-15	1111	Divide-by-16
0000	Divide-by-1										
0001	Divide-by-2										
.....											
1110	Divide-by-15										
1111	Divide-by-16										
-	Reserved. Always write as 1.										

59.8.13 Interrupt Status (uSDHCx_INT_STATUS)

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For Card Interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the Card Driver services the interrupt condition, otherwise the CINT bit will be asserted again.

The table below shows the relationship between the Command Timeout Error and the Command Complete.

Table 59-8. uSDHC Status for Command Timeout Error/Command Complete Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the Transfer Complete and the Data Timeout Error.

Table 59-9. uSDHC Status for Data Timeout Error/Transfer Complete Bit Combinations

Transfer Complete	Data Timeout Error	Meaning of the Status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data Transfer Complete

The table below shows the relationship between the Command CRC Error and Command Timeout Error.

Table 59-10. uSDHC Status for Command CRC Error/Command Timeout Error Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	No error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

uSDHCx_INT_STATUS field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28 DMAE	<p>DMA Error</p> <p>Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. This error can be caused by either Simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Since any error corrupts the whole data block, the Host Driver shall re-start the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size.</p> <p>1 Error 0 No Error</p>
27 Reserved	This read-only field is reserved and always has the value 0.
26 TNE	<p>Tuning Error: (only for SD3.0 SDR104 mode)</p> <p>This bit is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, Host Driver needs to abort a command executing and perform tuning.</p>
25 Reserved	This read-only field is reserved and always has the value 0.
24 AC12E	<p>Auto CMD12 Error</p> <p>Occurs when detecting that one of the bits in the Auto CMD12 Error Status register has changed from 0 to 1. This bit is set to 1, not only when the errors in Auto CMD12 occur, but also when the Auto CMD12 is not executed due to the previous command error.</p> <p>1 Error 0 No Error</p>
23 Reserved	This read-only field is reserved and always has the value 0.
22 DEBE	<p>Data End Bit Error</p> <p>Occurs either when detecting 0 at the end bit position of read data, which uses the DATA line, or at the end bit position of the CRC.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Error 0 No Error</p>

Table continues on the next page...

uSDHCx_INT_STATUS field descriptions (continued)

Field	Description
21 DCE	<p>Data CRC Error</p> <p>Occurs when detecting a CRC error when transferring read data, which uses the DATA line, or when detecting the Write CRC status having a value other than 010.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Error 0 No Error</p>
20 DIOE	<p>Data Timeout Error</p> <p>Occurs when detecting one of following time-out conditions.</p> <ul style="list-style-type: none"> • Busy time-out for R1b, R5b type • Busy time-out after Write CRC status • Read Data time-out. <p>This bit will be not asserted in tuning process.</p> <p>1 Time out 0 No Error</p>
19 CIE	<p>Command Index Error</p> <p>Occurs if a Command Index error occurs in the command response.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Error 0 No Error</p>
18 CEBE	<p>Command End Bit Error</p> <p>Occurs when detecting that the end bit of a command response is 0.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 End Bit Error Generated 0 No Error</p>
17 CCE	<p>Command CRC Error</p> <p>Command CRC Error is generated in two cases.</p> <ul style="list-style-type: none"> • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this bit is set when detecting a CRC error in the command response. • The uSDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then the uSDHC shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict. <p>This bit will be not asserted in tuning process.</p> <p>1 CRC Error Generated. 0 No Error</p>
16 CTOE	<p>Command Timeout Error</p> <p>Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the uSDHC detects a CMD line conflict, in which case a Command CRC Error shall also be set (as shown in Interrupt Status (uSDHC_INT_STATUS)), this bit shall be set without waiting for 64 SDCLK cycles. This is because the command will be aborted by the uSDHC.</p>

Table continues on the next page...

uSDHCx_INT_STATUS field descriptions (continued)

Field	Description
	This bit will be not asserted in tuning process. 1 Time out 0 No Error
15 Reserved	This read-only field is reserved and always has the value 0.
14 TP	Tuning Pass:(only for SD3.0 SDR104 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
13 Reserved	This read-only field is reserved and always has the value 0.
12 RTE	Re-Tuning Event: (only for SD3.0 SDR104 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. Host Controller requests Host Driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 1 Re-Tuning should be performed 0 Re-Tuning is not required
11–9 Reserved	This read-only field is reserved and always has the value 0.
8 CINT	Card Interrupt This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the uSDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the Host System. Writing this bit to 1 can clear this bit, but as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. When this status has been set, and the Host Driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset the interrupt sources in the SDIO card and the interrupt signal may not be asserted), write 1 to clear this bit, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 1 Generate Card Interrupt 0 No Card Interrupt
7 CRM	Card Removal This status bit is set if the Card Inserted bit in the Present State register changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. In order to leave it cleared, clear the Card Removal Status Enable bit in Interrupt Status Enable register. 1 Card removed 0 Card state unstable or inserted
6 CINS	Card Insertion This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State

Table continues on the next page...

uSDHCx_INT_STATUS field descriptions (continued)

Field	Description
	<p>register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if a card is inserted. In order to leave it cleared, clear the Card Inserted Status Enable bit in Interrupt Status Enable register.</p> <p>1 Card inserted 0 Card state unstable or removed</p>
5 BRR	<p>Buffer Read Ready</p> <p>This status bit is set if the Buffer Read Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Read Enable bit in the Present State register for additional information.</p> <p>This bit indicates that cmd19 is finished in tuning process.</p> <p>1 Ready to read buffer 0 Not ready to read buffer</p>
4 BWR	<p>Buffer Write Ready</p> <p>This status bit is set if the Buffer Write Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Write Enable bit in the Present State register for additional information.</p> <p>1 Ready to write buffer: 0 Not ready to write buffer</p>
3 DINT	<p>DMA Interrupt</p> <p>Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set. Either Simple DMA or ADMA finishes data transferring, this bit will be set.</p> <p>1 DMA Interrupt is generated 0 No DMA Interrupt</p>
2 BGE	<p>Block Gap Event</p> <p>If the Stop At Block Gap Request bit in the Protocol Control register is set, this bit is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this bit is not set to 1.</p> <p>In the case of a Read Transaction: This bit is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD Bus timing). The Read Wait must be supported in order to use this function.</p> <p>In the case of Write Transaction: This bit is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing).</p> <p>1 Transaction stopped at block gap 0 No block gap event</p>
1 TC	<p>Transfer Complete</p> <p>This bit is set when a read or write transfer is completed.</p> <p>In the case of a Read Transaction: This bit is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request bit in the Protocol Control register (after valid data has been read to the Host System).</p>

Table continues on the next page...

uSDHCx_INT_STATUS field descriptions (continued)

Field	Description
	<p>In the case of a Write Transaction: This bit is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request bit in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released).</p> <p>In the case of a command with busy, this bit is set when busy is deasserted.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Transfer complete 0 Transfer not complete</p>
0 CC	<p>Command Complete</p> <p>This bit is set when you receive the end bit of the command response (except Auto CMD12). Refer to the Command Inhibit (CMD) in the Present State register.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Command complete 0 Command not complete</p>

59.8.14 Interrupt Status Enable (uSDHCx_INT_STATUS_EN)

Setting the bits in this register to 1 enables the corresponding Interrupt Status to be set by the specified event. If any bit is cleared, the corresponding Interrupt Status bit is also cleared (i.e. when the bit in this register is cleared, the corresponding bit in Interrupt Status Register is always 0).

- Depending on IABG bit setting, uSDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the Card Interrupt, asserted from the card, to the time the Host System is informed.
- To detect a CMD line conflict, the Host Driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

59.8.15 Interrupt Signal Enable (uSDHCx_INT_SIGNAL_EN)

This register is used to select which interrupt status is indicated to the Host System as the interrupt. These status bits all share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

59.8.16 Auto CMD12 Error Status (uSDHCx_AUTOCMD12_ERR_STATUS)

When the Auto CMD12 Error Status bit in the Status register is set, the Host Driver shall check this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in bit 04-01. This register is valid only when the Auto CMD12 Error status bit is set.

The table below shows the relationship between the Auto CMD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 59-11. Relationship Between Command CRC Error and Command Timeout Error for Auto CMD12

Auto CMD12 CRC Error	Auto CMD12 Timeout Error	Type of Error
0	0	No Error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the uSDHC is going to issue an Auto CMD12.
 - Set bit 0 to 1 if the Auto CMD12 can't be issued due to an error in the previous command
 - Set bit 0 to 0 if the Auto CMD12 is issued
2. At the end bit of an Auto CMD12 response.
 - Check errors correspond to bits 1-4.
 - Set bits 1-4 corresponding to detected errors.
 - Clear bits 1-4 corresponding to detected errors
3. Before reading the Auto CMD12 Error Status bit 7.
 - Set bit 7 to 1 if there is a command that can't be issued
 - Clear bit 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, bit 7 shall be sampled when the driver is not writing to the Command register. So it is suggested to read this register only when the AC12E bit in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error bits (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

uSDHC Memory Map/Register Definition

Address: Base address + 3Ch offset

uSDHCx_AUTOCMD12_ERR_STATUS field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
23 SMP_CLK_SEL	<p>Sample Clock Select</p> <p>When std_tuning_en bit is set, this bit is used to select sampling clock to receive CMD and DATA. Otherwise, this bit is reserved. This bit is set by ty tuning procedure and valid after the completion of tuning(When Execute Tuning is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this bit is meaningless and ignored. A tuning circuit is reset by writing to 0. This bit can be cleared with setting Execute Tuning. Once the tuning circuit is reset, it will take time to complete tuning sequence. Therefore, Host Driver should keep this bit to 1 to perform re-tuning sequence to complete re-tuning sequence in a short time. Change of this bit is not allowed while the Host controller us receiving response or a read data block.</p>

Table continues on the next page...

uSDHCx_AUTOCMD12_ERR_STATUS field descriptions (continued)

Field	Description
	1 Tuned clock is used to sample data 0 Fixed clock is used to sample data
22 EXECUTE_TUNING	Execute Tuning When std_tuning_en bit is set, this bit is used to start tuning procedure. Otherwise, this bit is reserved. This bit is set to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to sam_clk_sel bit. Tuning procedure is aborted by writing 0.
21–8 Reserved	This read-only field is reserved and always has the value 0.
7 CNIBAC12E	Command Not Issued By Auto CMD12 Error Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register. 1 Not Issued 0 No error
6–5 Reserved	This read-only field is reserved and always has the value 0.
4 AC12IE	Auto CMD12 / 23 Index Error Occurs if the Command Index error occurs in response to a command. 1 Error, the CMD index in response is not CMD12/23 0 No error
3 AC12CE	Auto CMD12 / 23 CRC Error Occurs when detecting a CRC error in the command response. 1 CRC Error Met in Auto CMD12/23 Response 0 No CRC error
2 AC12EBE	Auto CMD12 / 23 End Bit Error Occurs when detecting that the end bit of command response is 0 which should be 1. 1 End Bit Error Generated 0 No error
1 AC12TOE	Auto CMD12 / 23 Timeout Error Occurs if no response is returned within 64 SDCLK cycles from the end bit of the command. If this bit is set to 1, the other error status bits (2-4) have no meaning. 1 Time out 0 No error
0 AC12NE	Auto CMD12 Not Executed If memory multiple block data transfer is not started, due to a command error, this bit is not set because it is not necessary to issue an Auto CMD12. Setting this bit to 1 means the uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (1-4) have no meaning. 1 Not executed 0 Executed

59.8.17 Host Controller Capabilities (uSDHCx_HOST_CTRL_CAP)

This register provides the Host Driver with information specific to the uSDHC implementation. The value in this register is the power-on-reset value, and does not change with a software reset.

Address: Base address + 40h offset

uSDHCx_WTMK_LVL field descriptions

Field	Description
31-29 Reserved	This read-only field is reserved and always has the value 0.
28-24 WR_BRST_ LEN[4:0]	Write Burst Length ¹ The number of words the uSDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field).
23-16 WR_WML[7:0]	Write Watermark Level The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15-13 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

uSDHCx_WTMK_LVL field descriptions (continued)

Field	Description
12-8 RD_BRST_LEN[4:0]	Read Burst Length ² The number of words the uSDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field).
RD_WML[7:0]	Read Watermark Level The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.

1. Due to system restriction, the actual burst length may not exceed 16.
2. Due to system restriction, the actual burst length may not exceed 16.

59.8.19 Mixer Control (uSDHCx_MIX_CTRL)

This register is used to DMA and data transfer. To prevent data loss, The software should check if data transfer is active before writing this register. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

Table 59-12. Transfer Type Register Setting for Various Transfer Types

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

Address: Base address + 48h offset

uSDHCx_MIX_CTRL field descriptions

Field	Description
31 -	Reserved. Always write as 1
30 -	Reserved. Always write as 0.
29 -	Reserved. Always write as 0.
28–26 -	This field is reserved. Reserved
25 FBCLK_SEL	Feedback Clock Source Selection (Only used for SD3.0, SDR104 mode) 1 Feedback clock comes from the ipp_card_clk_out 0 Feedback clock comes from the loopback CLK
24 AUTO_TUNE_EN	Auto Tuning Enable (Only used for SD3.0, SDR104 mode) 1 Enable auto tuning 0 Disable auto tuning
23 SMP_CLK_SEL	When STD_TUNING_EN is 0, this bit is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode) 1 Tuned clock is used to sample data / cmd 0 Fixed clock is used to sample data / cmd
22 EXE_TUNE	Execute Tuning: (Only used for SD3.0, SDR104 mode) When STD_TUNING_EN is 0, this bit is set to 1 to indicate the Host Driver is starting tuning procedure. Tuning procedure is aborted by writing 0. 1 Execute Tuning 0 Not Tuned or Tuning Completed
21–8 Reserved	This read-only field is reserved and always has the value 0.
7 AC23EN	Auto CMD23 Enable When this bit is set to 1, the Host Controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	In DDR 4-bit mode nibble position indication. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single Block Select This bit enables multiple block DATA line data transfers. For any other commands, this bit can be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to Command Transfer Type (uSDHC_CMD_XFR_TYP)). 1 Multiple Blocks 0 Single Block
4 DTDSEL	Data Transfer Direction Select This bit defines the direction of DATA line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the uSDHC and is set to 0 for all other commands.

Table continues on the next page...

uSDHCx_MIX_CTRL field descriptions (continued)

Field	Description
	1 Read (Card to Host) 0 Write (Host to Card)
3 DDR_EN	Dual Data Rate mode selection
2 AC12EN	Auto CMD12 Enable Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the uSDHC will issue a CMD12 automatically when the last block transfer has completed. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the uSDHC will ignore this bit no matter it is set or not. 1 Enable 0 Disable
1 BCEN	Block Count Enable This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 1 Enable 0 Disable
0 DMAEN	DMA Enable This bit enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the Host Driver sets the DPSEL bit of this register. Whether the Simple DMA or the Advanced DMA is active depends on the DMA Select field of the Protocol Control register. 1 Enable 0 Disable

59.8.20 Force Event (uSDHCx_FORCE_EVENT)

The Force Event Register is not a physically implemented register. Rather, it is an address at which the Interrupt Status Register can be written if the corresponding bit of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding bit of Interrupt Status Register. A read from this register always results in 0's. In order to change the corresponding status bits in the Interrupt Status Register, make sure to set IPGEN bit in System Control Register so that IPG_CLK is always active.

Forcing a card interrupt will generate a short pulse on the DATA1 line, and the driver may treat this interrupt as a normal interrupt. The interrupt service routine may skip polling the card interrupt factor as the interrupt is self cleared.

Address: Base address + 50h offset

uSDHCx_FORCE_EVENT field descriptions

Field	Description
31 FEVTCINT	Force Event Card Interrupt Writing 1 to this bit generates a short low-level pulse on the internal DATA1 line, as if a self clearing interrupt was received from the external card. If enabled, the CINT bit will be set and the interrupt service routine may treat this interrupt as a normal interrupt from the external card.
30–29 Reserved	This read-only field is reserved and always has the value 0.
28 FEVTDMAE	Force Event DMA Error Forces the DMAE bit of Interrupt Status Register to be set.
27 Reserved	This read-only field is reserved and always has the value 0.
26 FEVTTNE	Force Tuning Error Forces the TNE bit of Interrupt Status Register to be set.
25 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

uSDHCx_FORCE_EVENT field descriptions (continued)

Field	Description
24 FEVTAC12E	Force Event Auto Command 12 Error Forces the AC12E bit of Interrupt Status Register to be set.
23 Reserved	This read-only field is reserved and always has the value 0.
22 FEVTDEBE	Force Event Data End Bit Error Forces the DEBE bit of Interrupt Status Register to be set.
21 FEVTDCE	Force Event Data CRC Error Forces the DCE bit of Interrupt Status Register to be set.
20 FEVTDTOE	Force Event Data Time Out Error Force the DTOE bit of Interrupt Status Register to be set.
19 FEVTCIE	Force Event Command Index Error Forces the CCE bit of Interrupt Status Register to be set.
18 FEVTCBE	Force Event Command End Bit Error Forces the CEBE bit of Interrupt Status Register to be set.
17 FEVTCCE	Force Event Command CRC Error Forces the CCE bit of Interrupt Status Register to be set.
16 FEVTCIOE	Force Event Command Time Out Error Forces the CIOE bit of Interrupt Status Register to be set.
15–8 Reserved	This read-only field is reserved and always has the value 0.
7 FEVTCNIBAC12E	Force Event Command Not Executed By Auto Command 12 Error Forces the CNIBAC12E bit in the Auto Command12 Error Status Register to be set.
6–5 Reserved	This read-only field is reserved and always has the value 0.
4 FEVTAC12IE	Force Event Auto Command 12 Index Error Forces the AC12IE bit in the Auto Command12 Error Status Register to be set.
3 FEVTAC12EBE	Force Event Auto Command 12 End Bit Error Forces the AC12EBE bit in the Auto Command12 Error Status Register to be set.
2 FEVTAC12CE	Force Event Auto Command 12 CRC Error Forces the AC12CE bit in the Auto Command12 Error Status Register to be set.
1 FEVTAC12TOE	Force Event Auto Command 12 Time Out Error Forces the AC12TOE bit in the Auto Command12 Error Status Register to be set.
0 FEVTAC12NE	Force Event Auto Command 12 Not Executed Forces the AC12NE bit in the Auto Command12 Error Status Register to be set.

59.8.21 ADMA Error Status Register (uSDHCx_ADMA_ERR_STATUS)

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- **ST_STOP:** Previous location set in the ADMA System Address register is the error descriptor address.
- **ST_FDS:** Current location set in the ADMA System Address register is the error descriptor address.
- **ST_CADR:** This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error.
- **ST_TFR:** Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the Host Driver should use the ACMD22 to get the number of the written block, rather than using this information, since unwritten data may exist in the Host Controller.

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The Host Driver can distinguish this error by reading the Valid bit of the error descriptor.

Table 59-13. ADMA Error State Coding

D01-D00	ADMA Error State (when error has occurred)	Contents of ADMA System Address Register
00	ST_STOP (Stop DMA)	Holds the address of the next executable Descriptor command
01	ST_FDS (Fetch Descriptor)	Holds the valid Descriptor address
10	ST_CADR (Change Address)	No ADMA Error is generated
11	ST_TFR (Transfer Data)	Holds the address of the next executable Descriptor command

uSDHC Memory Map/Register Definition

uSDHCx_ADMA_ERR_STATUS field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value 0.
3 ADMADCE	ADMA Descriptor Error This error occurs when invalid descriptor fetched by ADMA. 1 Error 0 No Error
2 ADMALME	ADMA Length Mismatch Error This error occurs in the following 2 cases: <ul style="list-style-type: none"> While the Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length. Total data length cannot be divided by the block length. 1 Error 0 No Error
ADMAES	ADMA Error State (when ADMA Error is occurred)

Table continues on the next page...

uSDHCx_ADMA_ERR_STATUS field descriptions (continued)

Field	Description
	This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. Refer to ADMA Error Status Register (uSDHCx_ADMA_ERR_STATUS) for more details.

59.8.22 ADMA System Address (uSDHCx_ADMA_SYS_ADDR)

This register contains the physical system memory address used for ADMA transfers.

Address: Base address + 58h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

uSDHCx_ADMA_SYS_ADDR field descriptions

Field	Description
31–2 ADS_ ADDR[31:0]	<p>ADMA System Address</p> <p>This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the Host Driver shall set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register shall hold the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.</p> <p>Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions .</p>
Reserved	This read-only field is reserved and always has the value 0.

59.8.23 DLL (Delay Line) Control (uSDHCx_DLL_CTRL)

This register contains control bits for DLL.

Address: Base address + 60h offset

uSDHCx_DLL_CTRL field descriptions

Field	Description
31–28 DLL_CTRL_REF_UPDATE_INT[3:0]	DLL control loop update interval. The interval cycle is $(2 + \text{REF_UPDATE_INT}) * \text{REF_CLOCK}$. By default, the DLL control loop shall update every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 DLL_CTRL_SLV_UPDATE_INT[7:0]	Slave delay line update interval. If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 Reserved	This read-only field is reserved and always has the value 0.
18–16 DLL_CTRL_SLV_DLY_TARGET1	Refer to DLL_CTRL_SLV_DLY_TARGET0 below.
15–9 DLL_CTRL_SLV_OVERRIDE_VAL[6:0]	When SLV_OVERRIDE = 1 This field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.

Table continues on the next page...

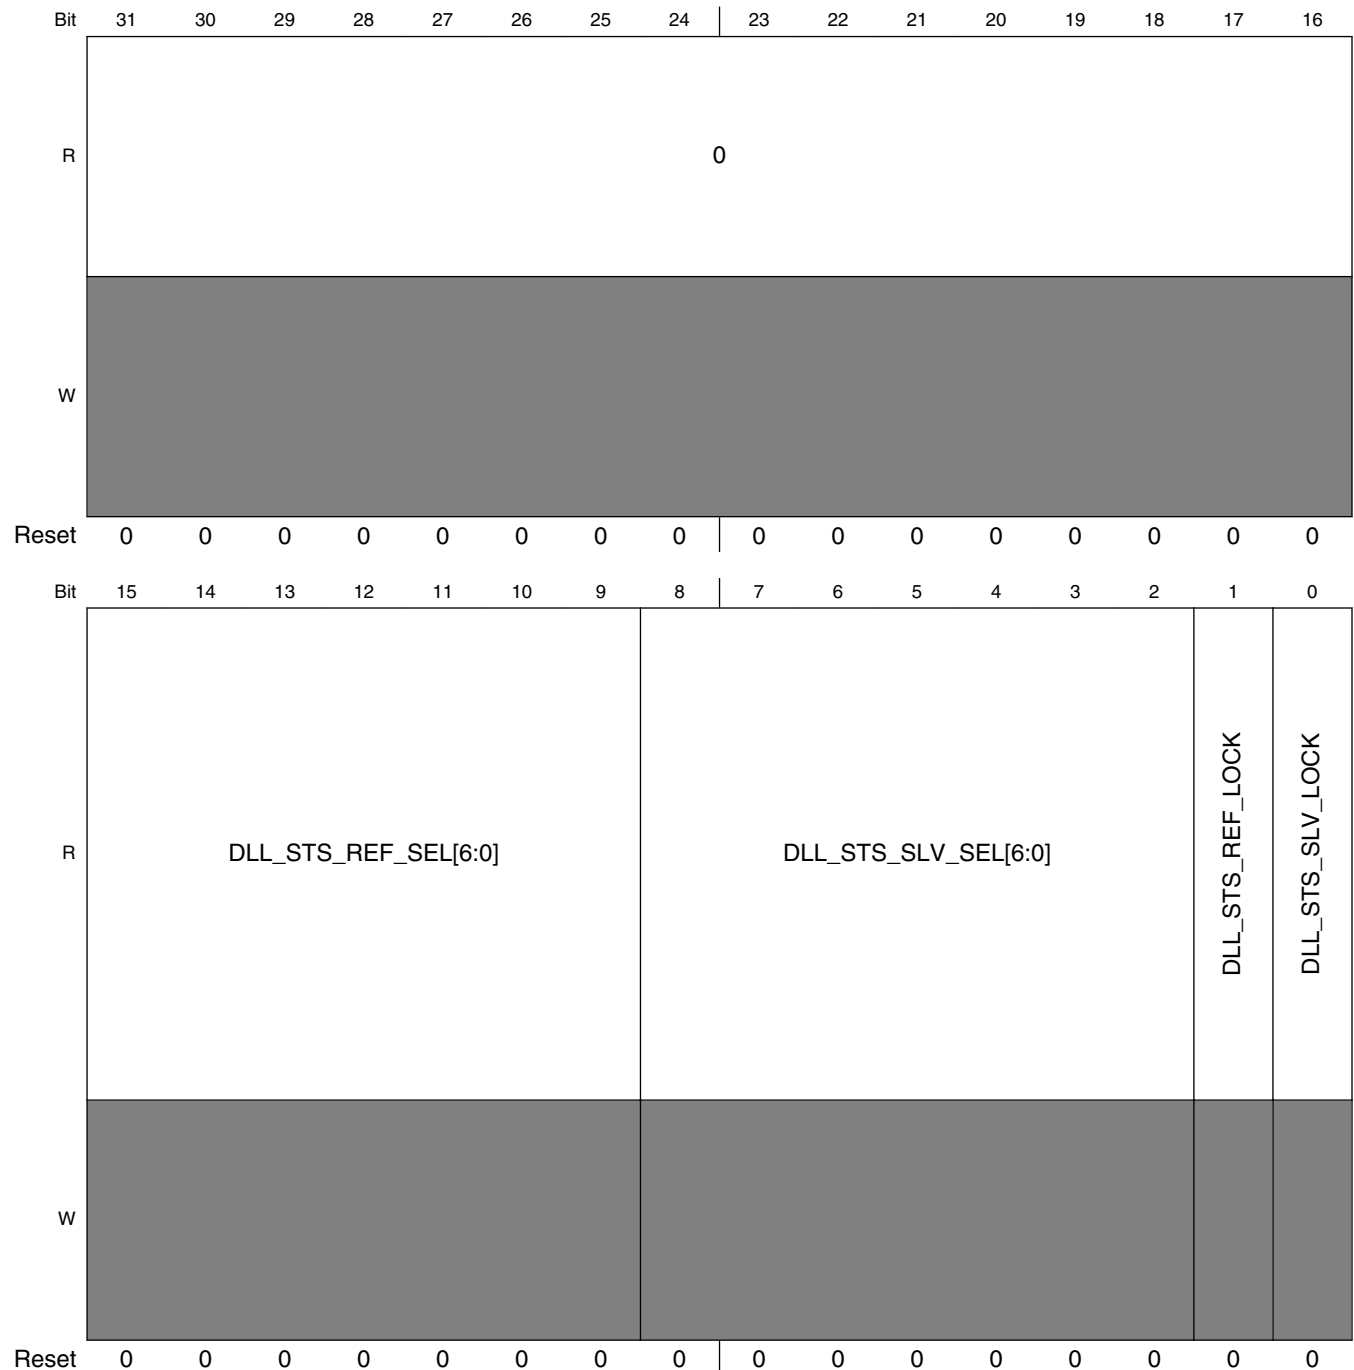

uSDHCx_DLL_CTRL field descriptions (continued)

Field	Description
8 DLL_CTRL_ SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7 DLL_CTRL_ GATE_UPDATE	Set this bit to 1 to prevent the DLL from updating (since when clock_in exists, glitches may appear during DLL updates). This bit may be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_ SLV_DLY_ TARGET0	The delay target for the uSDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. The delay is $((DLL_CTRL_SLV_DLY_TARGET1 + 1) * REF_CLOCK / 2) / 16$ So the input read-clock can be delayed relative input data from $(REF_CLOCK / 2) / 16$ to $REF_CLOCK * 4$.
2 DLL_CTRL_ SLV_FORCE_ UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function may not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_ RESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 DLL_CTRL_ ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE_VAL, the DLL does not need to be enabled.

59.8.24 DLL Status (uSDHCx_DLL_STATUS)

This register contains the DLL status information. All bits are read only and will read the same as the power-reset value.

Address: Base address + 64h offset

uSDHCx_DLL_STATUS field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–9 DLL_STS_REF_SEL[6:0]	Reference delay line select taps. This is encoded by 7 bits for 127 taps.
8–2 DLL_STS_SLV_SEL[6:0]	Slave delay line select status. This is the instant value generated from reference chain. Since the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

59.8.25 CLK Tuning Control and Status (uSDHCx_CLK_TUNE_CTRL_STATUS)

This register contains the Clock Tuning Control status information. All bits are read only and will read the same as the power-reset value. This register is added to support SD3.0 UHS-I SDR104 mode.

Address: Base address + 68h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

uSDHCx_CLK_TUNE_CTRL_STATUS field descriptions

Field	Description
31 PRE_ERR	PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.

Table continues on the next page...

uSDHCx_CLK_TUNE_CTRL_STATUS field descriptions (continued)

Field	Description
30–24 TAP_SEL_ PRE[6:0]	<p>Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE.</p> <p>When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE.</p> <p>When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE will be updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.</p>
23–20 TAP_SEL_ OUT[3:0]	Reflect the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19–16 TAP_SEL_ POST[3:0]	Reflect the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14–8 DLY_CELL_ SET_PRE[6:0]	Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.
7–4 DLY_CELL_ SET_OUT[6:0]	Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.
DLY_CELL_ SET_POST[6:0]	Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

59.8.26 Vendor Specific Register (uSDHCx_VEND_SPEC)

This register contains the vendor specific control / status register.

Address: Base address + C0h offset

1 VSELECT	<p>Voltage Selection</p> <p>Change the value of output signal VSELECT, to control the voltage on pads for external card. There must be a control circuit out of uSDHC to change the voltage on pads.</p> <p>1 Change the voltage to low voltage range, around 1.8 V</p> <p>0 Change the voltage to high voltage range, around 3.0 V</p>
0 EXT_DMA_EN	<p>External DMA Request Enable</p> <p>Enable the request to external DMA. When the internal DMA (either Simple DMA or Advanced DMA) is not in use, and this bit is set, uSDHC will send out DMA request when the internal buffer is ready. This bit is particularly useful when transferring data by ARM platform polling mode, and it is not allowed to send out the external DMA request. By default, this bit is set.</p> <p>0 In any scenario, uSDHC does not send out external DMA request.</p> <p>1 When internal DMA is not active, the external DMA request will be sent out.</p>

59.8.27 MMC Boot Register (uSDHCx_MMC_BOOT)

This register contains the MMC Fast Boot control register.

Address: Base address + C4h offset

uSDHCx_MMC_BOOT field descriptions

Field	Description
31–16 BOOT_BLK_CNT[15:0]	The value defines the Stop At Block Gap value of automatic mode. When received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT) and AUTO_SABG_EN is 1, then Stop At Block Gap. Here, BLK_CNT is defined in the Block Attributes Register, bit31 - 16 of 0x04.
15–9 Reserved	This read-only field is reserved and always has the value 0.
8 DISABLE_TIME_OUT	Disable Time Out NOTE: When this bit is set, there is no timeout check no matter whether BOOT_EN is set or not. 0 Enable time out 1 Disable time out
7 AUTO_SABG_EN	During boot, enable auto stop at block gap function. This function will be triggered, and host will stop at block gap when received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT).
6 BOOT_EN	Boot mode enable 0 Fast boot disable 1 Fast boot enable
5 BOOT_MODE	Boot mode select

Table continues on the next page...

uSDHCx_MMC_BOOT field descriptions (continued)

Field	Description
	0 Normal boot 1 Alternative boot
4 BOOT_ACK	Boot ACK mode select 0 No ack 1 Ack
DTOCV_ ACK[3:0]	Boot ACK time out counter value. 0000 SDCLK x 2 ¹³ 0001 SDCLK x 2 ¹⁴ 0010 SDCLK x 2 ¹⁵ 0011 SDCLK x 2 ¹⁶ 0100 SDCLK x 2 ¹⁷ 0101 SDCLK x 2 ¹⁸ 0110 SDCLK x 2 ¹⁹ 0111 SDCLK x 2 ²⁰ 1110 SDCLK x 2 ²⁷ 1111 SDCLK x 2 ²⁸

59.8.28 Vendor Specific 2 Register (uSDHCx_VEND_SPEC2)

This register contains the vendor specific control 2 register.

Address: Base address + C8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0		

uSDHCx_VEND_SPEC2 field descriptions

Field	Description
31–24 -	This field is reserved.
23 ACMD23_ ARGU2_EN	Default1 1 Argument2 register enable for ACMD23 sharing with SDMA system address register. Default is enable. 0 Disable
22–12 -	This field is reserved.
11–10 -	This field is reserved. Reserved
9 Reserved	This read-only field is reserved and always has the value 0.
8 Reserved	This read-only field is reserved and always has the value 0.
7 CARD_INT_ AUTO_CLR_DIS	Disable the feature to clear the Card interrupt status bit when Card Interrupt status enable bit is cleared. Only for debug. 0 Card interrupt status bit (CINT) can be cleared when Card Interrupt status enable bit is 0. 1 Card interrupt status bit (CINT) can only be cleared by writing a 1 to CINT bit.
6 TUNING_CMD_ EN	Enable the auto tuning circuit to check the CMD line. 0 Auto tuning circuit does not check the CMD line. 1 Auto tuning circuit checks the CMD line.
5 TUNING_1bit_EN	Enable the auto tuning circuit to check the DATA0 only. It is used with the TUNING_8bit_EN together.
4 TUNING_8bit_EN	Enable the auto tuning circuit to check the DATA[7:0]. It is used with the TUNING_1bit_EN together. NOTE: The format of these two bits are [TUNNING_8bit_EN:TUNNING_1bit_EN]. 00 Tuning circuit only checks the DATA[3:0]. 01 Tuning circuit only checks the DATA0. 10 Tuning circuit checks the whole DATA[7:0]. 11 Invalid.
3 CARD_INT_D3_ TEST	Card Interrupt Detection Test This bit only uses for debugging. 0 Check the card interrupt only when DATA3 is high. 1 Check the card interrupt by ignoring the status of DATA3.
2 SDR104_NSD_ DIS	Interrupt window after abort command is sent. This bit only uses for debugging. 0 Enable the interrupt window 9 cycles later after the end of the I/O abort command (or CMD12) is sent. 1 Enable the interrupt window 5 cycles later after the end of the I/O abort command (or CMD12) is sent.
1 SDR104_OE_ DIS	CMD_OE / DATA_OE logic generation test. This bit only uses for debugging.

Table continues on the next page...

uSDHCx_VEND_SPEC2 field descriptions (continued)

Field	Description
	0 Drive the CMD_OE / DATA_OE for one more clock cycle after the end bit. 1 Stop to drive the CMD_OE / DATA_OE at once after driving the end bit.
0 SDR104_ TIMING_DIS	Timeout counter test. This bit only uses for debugging. 0 The timeout counter for Ncr changes to 80, Ncrc changes to 21. 1 The timeout counter for Ncr changes to 72, Ncrc changes to 15.

59.8.29 Tuning Control Register (uSDHCx_TUNING_CTRL)

The register contains configuration of tuning circuit.

Address: Base address + CCh offset

uSDHCx_TUNING_CTRL field descriptions

Field	Description
31–25 -	Reserved
24 STD_TUNING_EN	Standard tuning circuit and procedure enable: This bit is used to enable standard tuning circuit and procedure.
23 -	Reserved
22–20 TUNING_WINDOW	Select data window value for auto tuning
19 -	Reserved
18–16 TUNING_STEP	The increasing delay cell steps in tuning procedure.
15–8 TUNING_COUNTER	The MAX repeat CMD19 times in tuning procedure.
TUNING_START_TAP	The start dealy cell point when send first CMD19 in tuning procedure.

Chapter 60

Watchdog Timer (WDOG)

60.1 Overview

The Watchdog Timer (WDOG) protects against system failures by providing a method by which to escape from unexpected events or programming errors.

Once the WDOG is activated, it must be serviced by the software on a periodic basis. If servicing does not take place, the timer times out. Upon timeout, the WDOG asserts the internal system reset signal, WDOG_RESET_B_DEB to the System Reset Controller (SRC).

There is also a provision for WDOG signal assertion by timeout counter expiration. There is an option of programmable interrupt generation before the counter actually times out. The time at which the interrupt needs to be generated prior to counter timeout is programmable. There is a power down counter which is enabled out of any reset (POR, Warm/Cold). This counter has a fixed timeout period of 16 seconds, upon which it asserts the WDOG signal.

Flow diagrams for the timeout counter, power down counter and interrupt operations are shown in [Flow Diagrams](#).

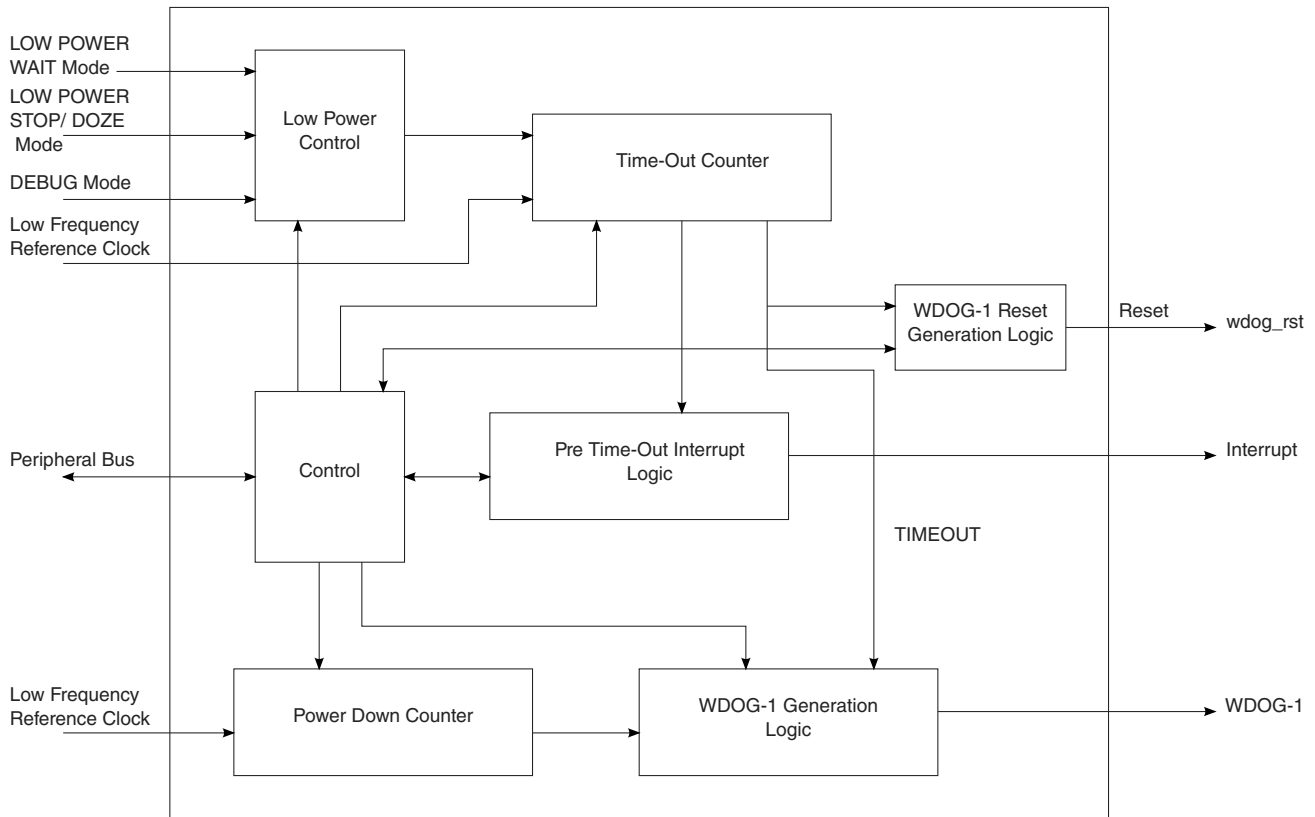

Figure 60-1. WDOG Diagram

60.1.1 Features

The WDOG features are listed below:

- Configurable timeout counter with timeout periods from 0.5 to 128 seconds which, after timeout expiration, result in the assertion of WDOG_RESET_B_DEB reset signal .
- Time resolution of 0.5 seconds
- Configurable timeout counter that can be programmed to run or stop during low-power modes
- Configurable timeout counter that can be programmed to run or stop during DEBUG mode
- Programmable interrupt generation prior to timeout
- The duration between interrupt and timeout events can be programmed from 0 to 127.5 seconds in steps of 0.5 seconds.
- Power down counter with fixed timeout period of 16 seconds, which if not disabled after reset will assert WDOG_B signal low

- Power down counter will be enabled out of any reset (POR, Warm / Cold reset) by default.

60.2 External signals

Table 60-1. WDOG External Signals

Signal	Description	Pad	Mode	Direction
WDOG1_ANY	Global WDOG signal	ENET2_RX_ER	ALT8	IO
		GPIO1_IO09	ALT1	
		LCD_DATA19	ALT2	
		LCD_RESET	ALT4	
WDOG1_B	This signal will power down the chip.	GPIO1_IO01	ALT8	IO
		GPIO1_IO08	ALT1	
		UART3_RTS_B	ALT8	
WDOG1_RST_B_DEB	This signal is a reset source for the chip.	ENET1_TX_DATA1	ALT8	O
		LCD_CLK	ALT8	
WDOG2_B	This signal will power down the chip.	LCD_VSYNC	ALT4	IO
WDOG2_RST_B_DEB	This signal is a reset source for the chip.	ENET1_TX_EN	ALT8	O
WDOG3_B	This signal will power down the chip.	GPIO1_IO00	ALT8	IO
WDOG3_RST_B_DEB	This signal is a reset source for the chip.	LCD_HSYNC	ALT4	O

60.3 Clocks

This section describes clocks and special clocking requirements of the block.

The WDOG uses the low frequency reference clock for its counter and control operations. The peripheral bus clock is used for register read/write operations.

The following table describes the clock sources for WDOG. Please see [Introduction](#) for clock setting, configuration and gating information.

Table 60-2. WDOG Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	IP Global functional clock. All functionality inside the WDOG module is synchronized to this clock.
ipg_clk_s	ipg_clk_root	IP slave bus clock. This clock is synchronized to ipg_clk and is only used for register read/write operations.

Table continues on the next page...

Table 60-2. WDOG Clocks (continued)

Clock name	Clock Root	Description
ipg_clk_32k	ckil_sync_clk_root	Low frequency (32.768 kHz) clock that continues to run in low-power mode. It is assumed that the Clock Controller will provide this clock signal synchronized to ipg_clk in the normal mode, and switch to a non-synchronized signal in low-power mode when the ipg_clk is off.

60.4 Watchdog mechanism and system integration

There are two WDOG modules, WDOG1 and WDOG2 (TZ) in the chip. The modules are disabled by default (after reset). WDOG1 will be configured during boot while WDOG2 is dedicated for secure world purposes and will be activated by TZ software if required. The TZ watchdog (TZ watchdog) module protects against TZ starvation by providing a method of escaping normal mode and forcing a switch to the TZ mode. TZ starvation is a situation where the normal OS prevents switching to the TZ mode. Such a situation is undesirable as it can compromise the system's security.

Once the TZ WDOG module is activated, it must be serviced by TZ on a periodic basis. If servicing does not take place, the timer times out. Upon a timeout, the TZ WDOG asserts a TZ-mapped interrupt that forces switching to the TZ mode. If it is still not serviced, the TZ WDOG asserts a security violation signal to the CSU. The TZ WDOG module cannot be programmed or de-activated by normal mode software.

The WDOG modules operate as follows:

- If servicing does not take place, the timer times out and the wdog_rst_b signal is activated (low)
- Interrupt can be generated before the counter actually times out
- The wdog_rst_b signal can be activated by software
- There is a power-down counter which gets enabled out of any reset. This counter has a fixed timeout period of 16 seconds upon which it will assert the ipp_wdog_b signal.

The following figure shows the WDOG1 and WDOG2 connectivity at the system level.

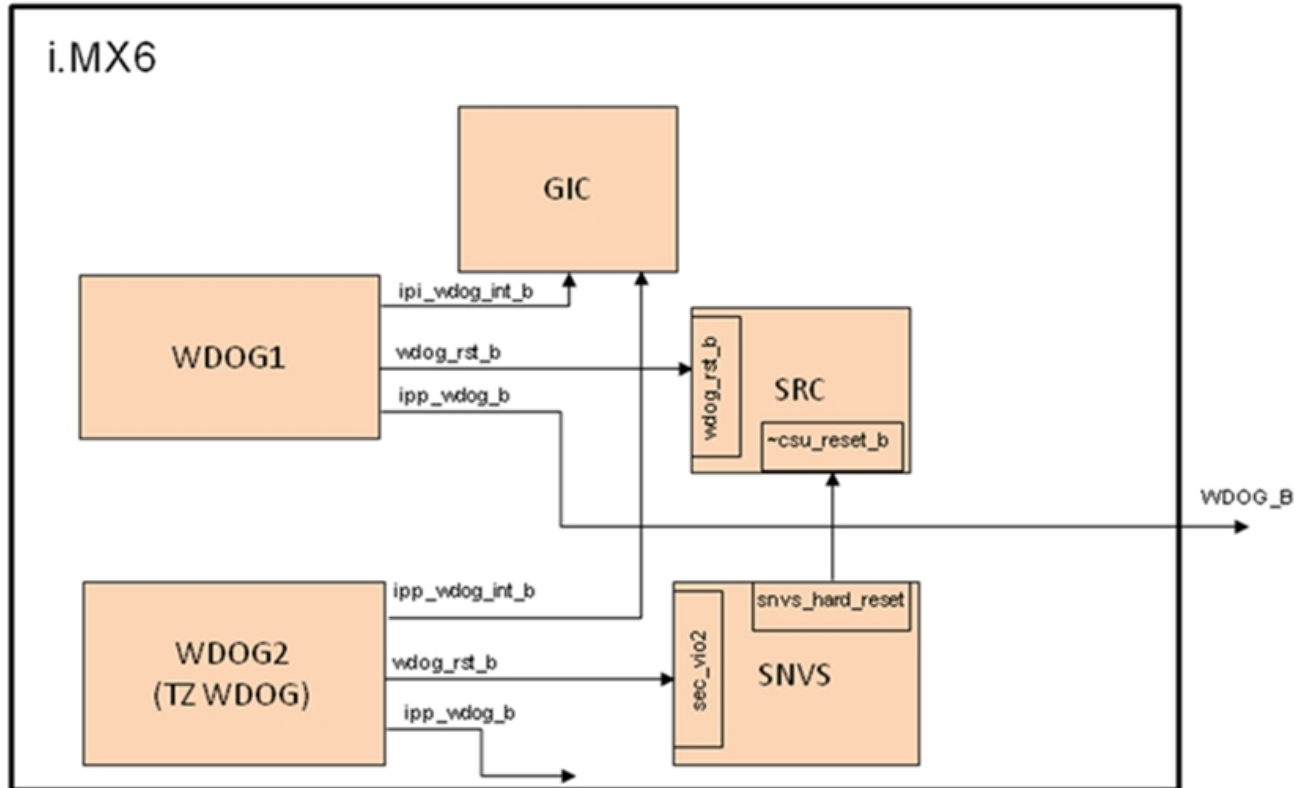

Figure 60-2. System integration

60.5 Functional description

This section provides a complete functional description of the block.

60.5.1 Timeout event

The WDOG provides timeout periods from 0.5 to 128 seconds with a time resolution of 0.5 seconds.

The user can determine the timeout period by writing to the WDOG timeout field (WT[7:0]) in the [Watchdog Control Register \(WDOG_WCR\)](#). The WDOG must be enabled by setting the WDE bit of [Watchdog Control Register \(WDOG_WCR\)](#) for the timeout counter to start running. After the WDOG is enabled, the counter is activated, loads the timeout value and begins to count down from this programmed value. The timer will time out when the counter reaches zero and the WDOG outputs a system reset signal, WDOG_RESET_B_DEB and asserts WDOG_B (WDT bit should be set in [Watchdog Control Register \(WDOG_WCR\)](#)).

However, the timeout condition can be prevented by reloading the counter with the new timeout value (WT[7:0] of WDOG_WCR) if a service routine (see [Servicing WDOG to reload the counter](#)) is performed before the counter reaches zero. If any system errors occur which prevent the software from servicing the [Watchdog Service Register \(WDOG_WSR\)](#), the timeout condition occurs. By performing the service routine, the WDOG reloads its counter to the timeout value indicated by bits WT[7:0] of the [Watchdog Control Register \(WDOG_WCR\)](#) and it restarts the countdown.

A system reset will reset the counter and place it in the idle state at any time during the countdown. The counter flow diagram is shown in [Flow Diagrams](#).

NOTE

The timeout value is reloaded to the counter either at the time WDOG is enabled or after the service routine has been performed.

60.5.1.1 Servicing WDOG to reload the counter

To reload a timeout value to the counter the proper service sequence begins by writing 0x_5555 followed by 0x_AAAA to the [Watchdog Service Register \(WDOG_WSR\)](#). Any number of instructions can be executed between the two writes. If the WDOG_WSR is not loaded with 0x_5555 prior to writing 0x_AAAA to the WDOG_WSR, the counter is not reloaded. If any value other than 0x_AAAA is written to the WDOG_WSR after 0x_5555, the counter is not reloaded. This service sequence will reload the counter with the timeout value WT[7:0] of [Watchdog Control Register \(WDOG_WCR\)](#). The timeout value can be changed at any point; it is reloaded when WDOG is serviced by the core.

60.5.2 Interrupt event

Prior to timeout, the WDOG can generate an interrupt which can be considered a warning that timeout will occur shortly.

The duration between interrupt event and timeout event can be controlled by writing to the WICT field of [Watchdog Interrupt Control Register \(WDOG_WICR\)](#). It can vary between 0 and 127.5 seconds. If the WDOG is serviced ([Servicing WDOG to reload the counter](#)) before the interrupt generation, the counter will be reloaded with the timeout value WT[7:0] of [Watchdog Control Register \(WDOG_WCR\)](#) and the interrupt will not be triggered.

60.5.3 Power-down counter event

The power-down counter inside WDOG will be enabled out of reset. This counter has a fixed timeout value of 16 seconds, after which it will drive the WDOG_B signal low.

To prevent this, the software must disable this counter by clearing the PDE bit of [Watchdog Miscellaneous Control Register \(WDOG_WMCR\)](#) within 16 seconds of reset deassertion. Once disabled, this counter can't be enabled again until the next system reset occurs. This feature is intended to prevent the hanging up of cores after reset, as WDOG is not enabled out of reset.

60.5.4 Low power modes

60.5.4.1 STOP and DOZE mode

If the WDOG timer disable bit for low power STOP and DOZE mode (WDZST) bit in the [Watchdog Control Register \(WDOG_WCR\)](#), is cleared, the WDOG timer continues to operate using the low frequency reference clock. If the low power enable (WDZST) bit is set, the WDOG timer operation will be suspended in low power STOP or DOZE mode. Upon exiting low power STOP or DOZE mode, the WDOG operation returns to what it was prior to entering the STOP or DOZE mode.

60.5.4.2 WAIT mode

If the WDOG timer disable bit for low power WAIT mode (WDW) bit in the [Watchdog Control Register \(WDOG_WCR\)](#), is cleared, the WDOG timer continues to operate using the low frequency reference clock. If the low power WAIT enable (WDW) bit is set, the WDOG timer operation will be suspended. Upon exiting low power WAIT mode, the WDOG operation returns to what it was prior to entering the WAIT mode.

NOTE

The WDOG timer won't be able to detect events that happen for periods shorter than one low frequency reference clock cycle. For example, in repeated WAIT mode entry or exit, if the RUN mode time is less than one low frequency reference clock cycle and if the WDW bit is set, the WDOG timer may never time out, even though the system is in RUN mode for a finite duration; WDOG may not see a low frequency reference clock edge during its wake time.

60.5.5 Debug mode

The WDOG timer can be configured for continual operation, or for suspension during debug mode. If the WDOG debug enable (WDBG) bit is set in the [Watchdog Control Register \(WDOG_WCR\)](#), the WDOG timer operation is suspended in debug mode. If the WDBG bit is set and the debug mode is entered, WDOG timer operation is suspended after two low frequency reference clocks. Similarly, WDOG timer operation continues after two low frequency reference clocks of debug mode exit. Register read and write accesses in debug mode continue to function normally. Also, while in debug mode, the WDE bit of [Watchdog Control Register \(WDOG_WCR\)](#) can be enabled/disabled directly. If the WDOG debug enable (WDBG) bit is cleared then WDOG timer operation is not suspended. The power-down counter is not affected by debug mode entry/exit.

NOTE

If the WDE bit of [Watchdog Control Register \(WDOG_WCR\)](#) is set/cleared while in debug mode, it remains set/cleared even after exiting debug mode.

60.5.6 Operations

60.5.6.1 Watchdog reset generation

The WDOG generated reset signal WDOG_RESET_B_DEB is asserted by the following operations:

- A software write to the Software Reset Signal (SRS) bit of the [Watchdog Control Register \(WDOG_WCR\)](#).
- WDOG timeout. See [Timeout event](#).

The $\overline{\text{wdog_rst}}$ will be asserted for one clock cycle of low frequency reference clock for both a timeout condition and a software write occurrence. It remains asserted for 1 clock cycle of low frequency reference clock even if a system reset is asserted in between. [Figure 60-4](#) shows the timing diagram of this signal due to a timeout condition.

60.5.6.2 WDOG_B generation

The WDOG asserts WDOG_B in the following scenarios:

- Software write to WDA bit of [Watchdog Control Register \(WDOG_WCR\)](#). WDOG_B signal remains asserted as long as the WDA bit is "0".
- WDOG timeout condition, WDT bit of [Watchdog Control Register \(WDOG_WCR\)](#) must be set for this scenario. A description of the timeout condition can be found in the [Timeout event](#). WDOG_B signal remains asserted until a power-on reset (POR) occurs. It gets cleared after the POR occurs (not due to any other system reset). [Figure 60-5](#) shows the timing diagram of WDOG_B due to timeout condition.
- WDOG power-down counter timeout, PDE bit of [Watchdog Miscellaneous Control Register \(WDOG_WMCR\)](#) should not be cleared for this scenario. A description of this counter can be found in the [Power-down counter event](#). WDOG_B signal remains asserted for one clock cycle of low frequency reference clock.

[Figure 60-3](#) shows the scenarios under which WDOG_B gets asserted.

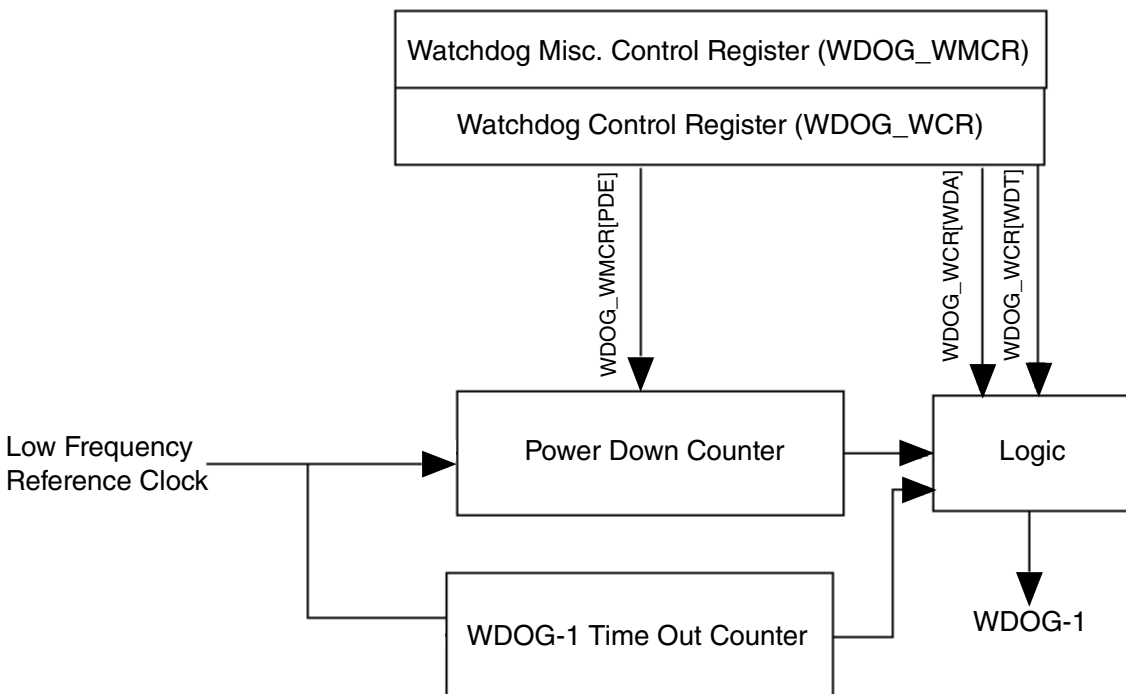

Figure 60-3. WDOG_B generation

Functional description

Figure 60-4. WDOG timeout condition/WDT bit is not set

Figure 60-5. WDOG timeout condition/WDT bit is set

60.5.7 Reset

The block is reset by a system reset and the WDOG counter will be disabled. The power-down counter is enabled and starts counting.

60.5.8 Interrupt

The WDOG has the feature of Interrupt generation before timeout.

The interrupt will be generated only if the WIE bit in [Watchdog Interrupt Control Register \(WDOG_WICR\)](#) is set. The exact time at which the interrupt should occur (prior to timeout) depends on the value of WICT field of [Watchdog Interrupt Control Register \(WDOG_WICR\)](#). For example, if the WICT field has a value 0x04, then the interrupt will be generated two seconds prior to timeout. Once the interrupt is triggered the WTIS bit in [Watchdog Interrupt Control Register \(WDOG_WICR\)](#) will be set. The software needs to clear this bit to deassert the interrupt. If the WDOG is serviced before the interrupt generation then the counter will be reloaded with the timeout value WT[7:0] of [Watchdog Control Register \(WDOG_WCR\)](#) and interrupt would not be triggered.

60.5.9 Flow Diagrams

A flow diagram of WDOG operation is shown below.

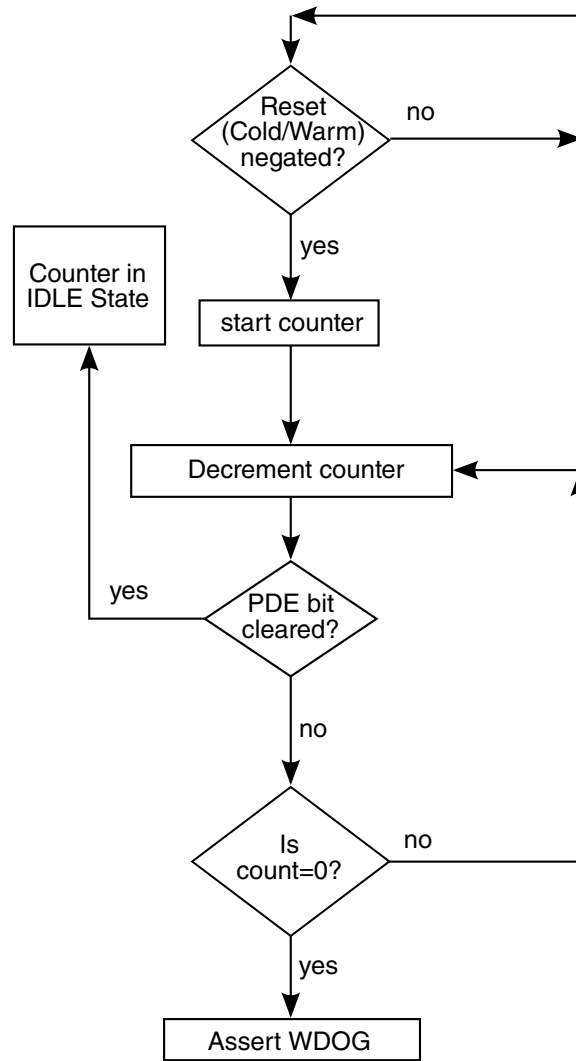

Figure 60-6. Power-Down Counter Flow Diagram

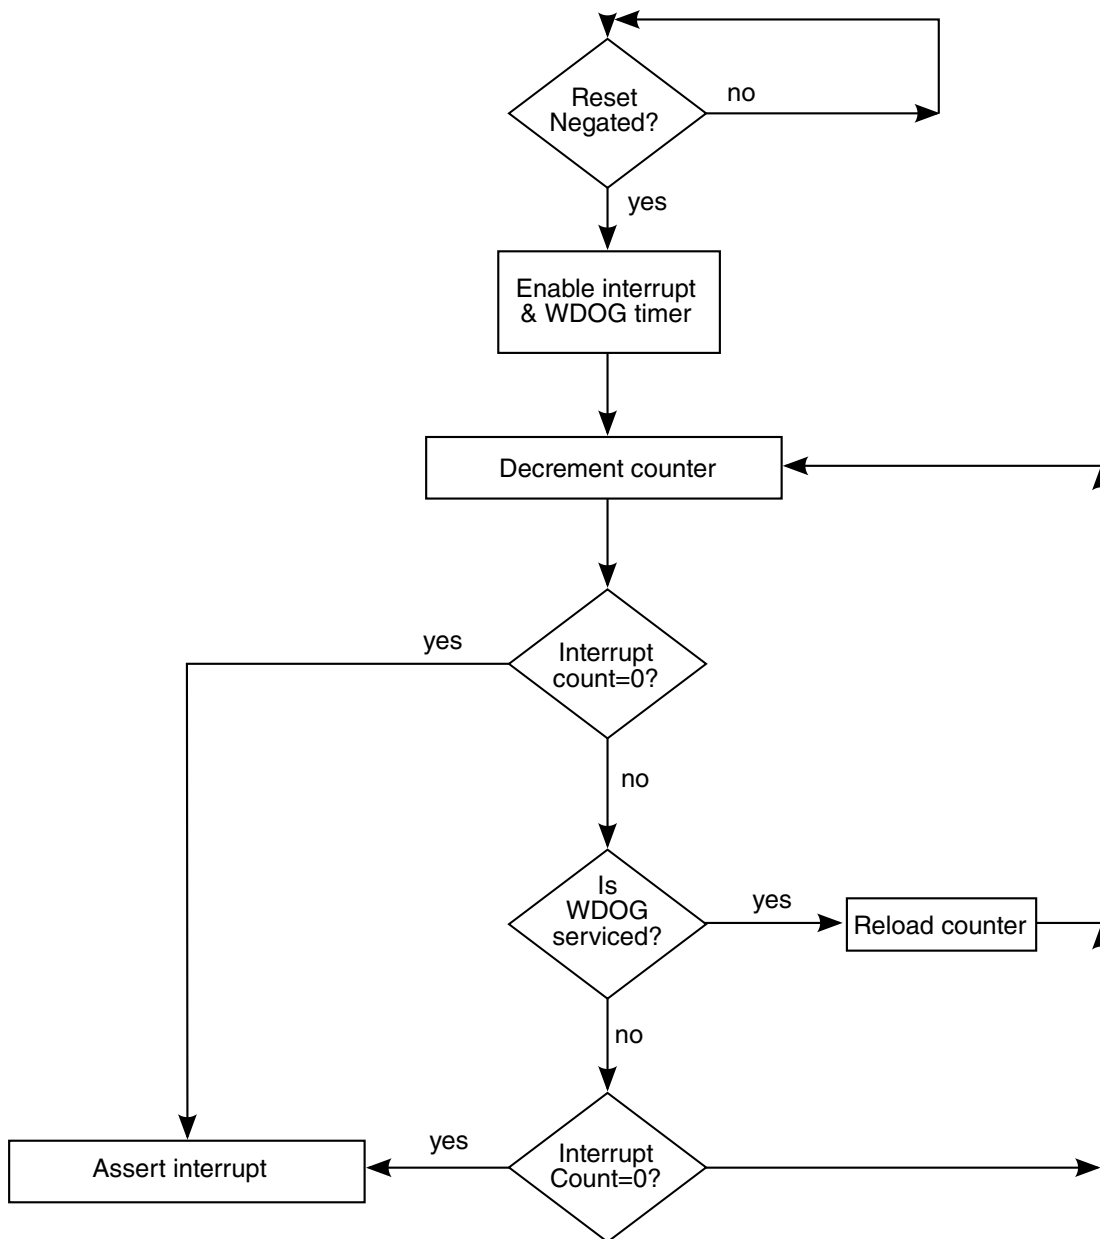

Figure 60-7. Interrupt Generation Flow Diagram

60.6 Initialization

The following sequence should be performed for WDOG initialization.

- PDE bit of [Watchdog Miscellaneous Control Register \(WDOG_WMCR\)](#) should be cleared to disable the power down counter.

- WT field of [Watchdog Control Register \(WDOG_WCR\)](#) should be programmed for sufficient timeout value.
- WDOG should be enabled by setting WDE bit of [Watchdog Control Register \(WDOG_WCR\)](#) so that the timeout counter loads the WT field value of [Watchdog Control Register \(WDOG_WCR\)](#) and starts counting.

60.7 WDOG Memory Map/Register Definition

The WDOG Memory Map/Register Definition can be found here.

The WDOG has user-accessible, 16-bit registers used to configure, operate, and monitor the state of the Watchdog Timer. Byte operations can be performed on these registers. If a 32-bit access is performed, the WDOG will not generate a peripheral bus error but will behave normally, like a 16-Bit access, making read/write possible. A 32-Bit access should be avoided, as the system may go to an unknown state.

WDOG memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
20B_C000	Watchdog Control Register (WDOG1_WCR)	16	R/W	0030h	60.7.1/3875

60.7.1 Watchdog Control Register (WDOGx_WCR)

The Watchdog Control Register (WDOG_WCR) controls the WDOG operation.

- WZST, WDBG and WDW are write-once only bits. Once the software does a write access to these bits, they will be locked and cannot be reprogrammed until the next system reset assertion.
- WDE is a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared until the next system reset.
- WDT is also a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared until the next POR. This bit does not get reset/cleared due to any system reset.

WDOGx_WCR field descriptions

Field	Description
15–8 WT	<p>Watchdog Time-out Field. This 8-bit field contains the time-out value that is loaded into the Watchdog counter after the service routine has been performed or after the Watchdog is enabled. After reset, WT[7:0] must have a value written to it before enabling the Watchdog otherwise count value of zero which is 0.5 seconds is loaded into the counter.</p> <p>NOTE: The time-out value can be written at any point of time but it is loaded to the counter at the time when WDOG is enabled or after the service routine has been performed. For more information see Timeout event .</p> <p>0x00 - 0.5 Seconds (Default). 0x01 - 1.0 Seconds. 0x02 - 1.5 Seconds. 0x03 - 2.0 Seconds. 0xff - 128 Seconds.</p>
7 WDW	<p>Watchdog Disable for Wait. This bit determines the operation of WDOG during Low Power WAIT mode. This is a write once only bit.</p> <p>0 Continue WDOG timer operation (Default). 1 Suspend WDOG timer operation.</p>
6 SRE	software reset extension, an option way to generate software reset

Table continues on the next page...

WDOGx_WCR field descriptions (continued)

Field	Description
	<p>adopt a new way to generate a more robust software reset. This bit can be set/clear with IP bus and will be reset with power-on reset .</p> <p>0 using original way to generate software reset (default) 1 using new way to generate software reset.</p>
5 WDA	<p>WDOG_B assertion. Controls the software assertion of the WDOG_B signal.</p> <p>0 Assert WDOG_B output. 1 No effect on system (Default).</p>
4 SRS	<p>Software Reset Signal. Controls the software assertion of the WDOG-generated reset signal WDOG_RESET_B_DEB . This bit automatically resets to "1" after it has been asserted to "0".</p> <p>NOTE: This bit does not generate the software reset to the block.</p> <p>0 Assert system reset signal. 1 No effect on the system (Default).</p>
3 WDT	<p>WDOG_B Time-out assertion. Determines if the WDOG_B gets asserted upon a Watchdog Time-out Event. This is a write-one once only bit.</p> <p>NOTE: There is no effect on WDOG_RESET_B_DEB (WDOG Reset) upon writing on this bit. WDOG_B gets asserted along with WDOG_RESET_B_DEB if this bit is set.</p> <p>0 No effect on WDOG_B (Default). 1 Assert WDOG_B upon a Watchdog Time-out event.</p>
2 WDE	<p>Watchdog Enable. Enables or disables the WDOG block. This is a write one once only bit. It is not possible to clear this bit by a software write, once the bit is set.</p> <p>NOTE: This bit can be set/reset in debug mode (exception).</p> <p>0 Disable the Watchdog (Default). 1 Enable the Watchdog.</p>
1 WDBG	<p>Watchdog DEBUG Enable. Determines the operation of the WDOG during DEBUG mode. This bit is write once only.</p> <p>0 Continue WDOG timer operation (Default). 1 Suspend the watchdog timer.</p>
0 WDZST	<p>Watchdog Low Power. Determines the operation of the WDOG during low-power modes. This bit is write once-only.</p> <p>NOTE: The WDOG can continue/suspend the timer operation in the low-power modes (STOP and DOZE mode).</p> <p>0 Continue timer operation (Default). 1 Suspend the watchdog timer.</p>

60.7.2 Watchdog Service Register (WDOGx_WSR)

When enabled, the WDOG requires that a service sequence be written to the Watchdog Service Register (WSR) to prevent the timeout condition.

NOTE

Executing the service sequence will reload the WDOG timeout counter.

Address: Base address + 2h offset

Bit	15	14	13	12	11	10	9	8		7	6	5	4	3	2	1	0
Read	WSR																
Write	WSR																
Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

WDOGx_WSR field descriptions

Field	Description
WSR	<p>Watchdog Service Register. This 16-bit field contains the Watchdog service sequence. Both writes must occur in the order listed prior to the time-out, but any number of instructions can be executed between the two writes. The service sequence must be performed as follows:</p> <p>0x5555 Write to the Watchdog Service Register (WDOG_WSR).</p> <p>0xAAAA Write to the Watchdog Service Register (WDOG_WSR).</p>

60.7.3 Watchdog Reset Status Register (WDOGx_WRSR)

The WRSR is a read-only register that records the source of the output reset assertion. It is not cleared by a hard reset. Therefore, only one bit in the WRSR will always be asserted high. The register will always indicate the source of the last reset generated due to WDOG. Read access to this register is with one wait state. Any write performed on this register will generate a Peripheral Bus Error .

A reset can be generated by the following sources, as listed in priority from highest to lowest:

- Watchdog Time-out
- Software Reset

Address: Base address + 4h offset

Bit	15	14	13	12		11	10	9	8
Read	0								
Write	0								
Reset	0	0	0	0		0	0	0	0
Bit	7	6	5	4		3	2	1	0
Read	0		POR		0		TOUT	SFTW	
Write	0		0		0		0	0	
Reset	0	0	0	0		0	0	0	0

WDOGx_WRSR field descriptions

Field	Description
15–5 Reserved	This read-only field is reserved and always has the value 0.
4 POR	Power On Reset. Indicates whether the reset is the result of a power on reset. 0 Reset is not the result of a power on reset. 1 Reset is the result of a power on reset.
3–2 Reserved	This read-only field is reserved and always has the value 0.
1 TOUT	Timeout. Indicates whether the reset is the result of a WDOG timeout. 0 Reset is not the result of a WDOG timeout. 1 Reset is the result of a WDOG timeout.
0 SFTW	Software Reset. Indicates whether the reset is the result of a WDOG software reset by asserting SRS bit 0 Reset is not the result of a software reset. 1 Reset is the result of a software reset.

60.7.4 Watchdog Interrupt Control Register (WDOGx_WICR)

The WDOG_WICR controls the WDOG interrupt generation.

Address: Base address + 6h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Read	WIE	WTIS	0						WICT								
Write		w1c															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

WDOGx_WICR field descriptions

Field	Description
15 WIE	Watchdog Timer Interrupt enable bit. Reset value is 0. NOTE: This bit is a write once only bit. Once the software does a write access to this bit, it will get locked and cannot be reprogrammed until the next system reset assertion 0 Disable Interrupt (Default). 1 Enable Interrupt.
14 WTIS	Watchdog Timer Interrupt Status bit will reflect the timer interrupt status, whether interrupt has occurred or not. Once the interrupt has been triggered software must clear this bit by writing 1 to it. 0 No interrupt has occurred (Default). 1 Interrupt has occurred
13–8 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

WDOGx_WICR field descriptions (continued)

Field	Description
WICT	<p>Watchdog Interrupt Count Time-out (WICT) field determines, how long before the counter time-out must the interrupt occur. The reset value is 0x04 implies interrupt will occur 2 seconds before time-out. The maximum value that can be programmed to WICT field is 127.5 seconds with a resolution of 0.5 seconds.</p> <p>NOTE: This field is write once only. Once the software does a write access to this field, it will get locked and cannot be reprogrammed until the next system reset assertion.</p> <p>0x00 WICT[7:0] = Time duration between interrupt and time-out is 0 seconds. 0x01 WICT[7:0] = Time duration between interrupt and time-out is 0.5 seconds. 0x04 WICT[7:0] = Time duration between interrupt and time-out is 2 seconds (Default). 0xff WICT[7:0] = Time duration between interrupt and time-out is 127.5 seconds.</p>

60.7.5 Watchdog Miscellaneous Control Register (WDOGx_WMCR)

WDOG_WMCR Controls the Power Down counter operation.

Address: Base address + 8h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Read	0															PDE	
Write	0																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

WDOGx_WMCR field descriptions

Field	Description
15–1 Reserved	This read-only field is reserved and always has the value 0.
0 PDE	<p>Power Down Enable bit. Reset value of this bit is 1, which means the power down counter inside the WDOG is enabled after reset. The software must write 0 to this bit to disable the counter within 16 seconds of reset de-assertion. Once disabled this counter cannot be enabled again. See Power-down counter event for operation of this counter.</p> <p>NOTE: This bit is write-one once only bit. Once software sets this bit it cannot be reset until the next system reset.</p> <p>0 Power Down Counter of WDOG is disabled. 1 Power Down Counter of WDOG is enabled (Default).</p>

Chapter 61

Crystal Oscillator (XTALOSC)

61.1 Overview

This block comprises both the 24 MHz and 32 kHz implementation of a biased amplifier that when combined with a suitable external quartz crystal and external load capacitors, implements an oscillator.

The block includes means to:

- Accept an external clock source.
- Detect if the crystal frequency is close to 24 MHz or 32 kHz.
- Reduce the operating current via software after the oscillator has started (24 MHz specific feature)
- Supply another ~32 kHz clock source based off an independent internal oscillator if there is no oscillation sensed on the RTC_XTAL bumps(contacts) (32 kHz specific feature). The internal oscillator will provide clocks to the same on-chip modules as the external 32 kHz oscillator.
- Automatically switch to the external oscillation source when sensed on the RTC_XTAL bumps(contacts) (32 kHz specific feature).

61.2 External Signals

The table found here describes the external signals of XTALOSC:

Table 61-1. XTALOSC External Signals

Signal	Description	Pad	Mode	Direction
XTALOSC_REF_CLK_32K	32 kHz reference clock	ENET1_RX_EN	ALT2	O
		GPIO1_IO03	ALT3	
		JTAG_TCK	ALT6	

Table continues on the next page...

**Table 61-1. XTALOSC External Signals
(continued)**

Signal	Description	Pad	Mode	Direction
XTALOSC_REF_CLK_24M	24 MHz reference clock	ENET1_TX_DATA0	ALT2	O
		ENET2_TX_DATA0	ALT8	
		GPIO1_IO04	ALT3	
		JTAG_TRST_B	ALT6	
XTALOSC_REF_CLK_25M	25 MHz reference clock	ENET2_RX_EN	ALT8	O
		GPIO1_IO02	ALT3	
		JTAG_MOD	ALT3	
XTALOSC_REF_CLK1	XTALOSC reference clock 1	ENET1_TX_CLK	ALT4	O
		GPIO1_IO00	ALT3	
		GPIO1_IO04	ALT0	
XTALOSC_REF_CLK2	XTALOSC reference clock 2	ENET2_TX_CLK	ALT4	O
		GPIO1_IO01	ALT3	
		GPIO1_IO05	ALT0	

61.3 Crystal Oscillator 24 MHz

61.3.1 Oscillator Configuration (24 MHz)

The basic block diagram of the 24 MHz module configured as a crystal oscillator is shown below.

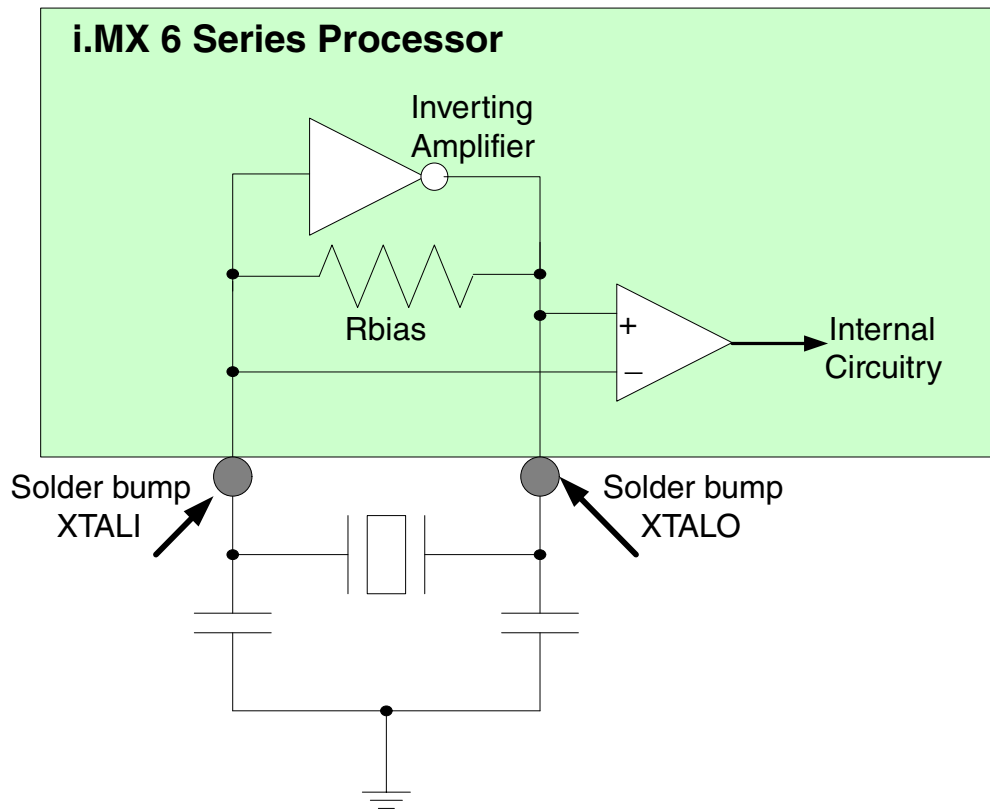

Figure 61-1. Oscillator Configuration (24 MHz)

This integrated biased amplifier can be used to create different frequency oscillators with different external component selection. However, care should be taken as many of the serial IO modules depend on the fixed frequency of 24 MHz. Please consult the sections of the document pertaining to the USB, ENET interfaces, for example. Once a healthy oscillation is established, then the bias current of the oscillator can generally be reduced to save power. This is accomplished through the XTALOSC24M_MISC0[OSC_I] bits, defined in the MISC0 register later in this chapter. Restore the XTALOSC24M_MISC0[OSC_I] bits before going into a power mode where the XTALOSC24 is powered down or oscillator startup may become an issue. The power down of the XTALOSC24 module is controlled by the CCM. See this section of the manual for more details.

61.3.2 RC Oscillator (24 MHz)

A lower-power RC oscillator module is available on-chip as a possible alternative to the 24 MHz crystal oscillator after a successful power-up sequence.

The 24 MHz RC oscillator is a self-tuning circuit that will output the programmed frequency value by using the RTC clock as it's reference. This oscillator is intended for normal operation and not fast boot.

While the power consumption of this RC oscillator is much lower than the 24 MHz crystal oscillator, one limitation of this RC oscillator module is that its clock frequency is not as accurate. Therefore, care should be observed when using this oscillator as the reference for the on-chip PLLs as their output clock frequency will be lower/higher than when using the 24 MHz crystal oscillator clock.

For more details on the possible usage of this module please contact a Freescale FAE for pertinent application-notes.

61.3.3 Crystal Frequency Detection(24 MHz)

A submodule exists that gives a fairly crude (relative to the accuracy of a crystal) estimation of whether the clock frequency is correct.

This function may be enabled by setting the XTALOSC24M_MISC0[OSC_XTALOK_EN] bit. It is disabled at system reset. When the oscillator is stable and the correct frequency is detected, the XTALOSC24M_MISC0[OSC_XTALOK] bit will be set. Note that the correct frequency will be observed before the oscillator fully blooms(the oscillation waveform build-up is completed).

61.4 Crystal Oscillator 32 kHz

61.4.1 Oscillator Configuration (32 kHz)

The basic block diagram of the 32 kHz module configured as a crystal oscillator is shown below.

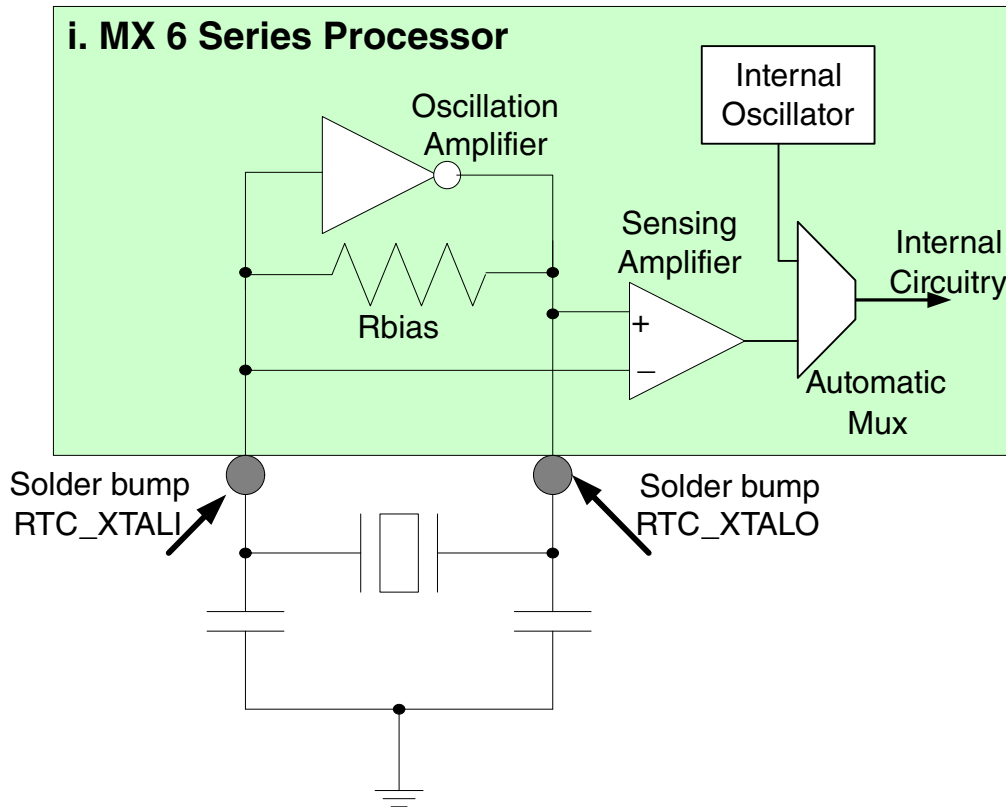

Figure 61-2. Oscillator Configuration (32 kHz)

This integrated biased amplifier can be used to create different frequency oscillators with different external component selection. Generally, RTC oscillators are either implemented with 32 kHz or 32.768 kHz crystals. Please consult the Security Reference Manual for appropriate frequency selection and configuration. Care must be taken to limit external leakage as this may debias the amplifier and degrade the gain.

The internal oscillator is automatically multiplexed in the clocking system when the system detects a loss of clock. The internal oscillator will provide clocks to the same on-chip modules as the external 32 kHz oscillator. The internal oscillator is not precise relative to a crystal. While it will provide a clock to the system, it generally will not be precise enough for long term time keeping. The internal oscillator is anticipated to be useful for quicker startup times, tampering prevention, and for cost savings in applications not needing the precision of an external crystal.

61.4.2 Bypass Configuration (32 kHz)

If it is desired to drive the chip with an external clock source, then the 32 kHz oscillator could be driven in one of three configurations using a nominal 1.1V source.

1. A single ended external clock source can be used to overdrive the output of the amplifier (RTC_XTALO). Since the oscillation sensing amplifier is differential, the RTC_XTALI pin should be externally floating and capacitively loaded. The combination of the internal biasing resistor and the external capacitor will filter the signal applied to the RTC_XTALO pin and develop a rough reference for the sensing amplifier to compare to.
2. A single ended external clock source can be used to drive RTC_XTALI. In this configuration, RTC_XTALO should be left externally floating.
3. A differential external clock source can be used to drive both RTC_XTALI and RTC_XTALO.

Generally, configuration 2 is anticipated to be the most used configuration, but all three configurations may be utilized.

61.5 XTALOSC 24MHz Memory Map/Register Definition

NOTE

The register content is mixed with analog functions not related to the oscillator function. These bits are noted.

XTALOSC24M memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
20C_8150	Miscellaneous Register 0 (XTALOSC24M_MISC0)	32	R/W	0400_0000h	61.5.1/3888
20C_8270	XTAL OSC (LP) Control Register (XTALOSC24M_LOWPWR_CTRL)	32	R/W	0000_4009h	61.5.2/3891
20C_8274	XTAL OSC (LP) Control Register (XTALOSC24M_LOWPWR_CTRL_SET)	32	R/W	0000_4009h	61.5.2/3891
20C_8278	XTAL OSC (LP) Control Register (XTALOSC24M_LOWPWR_CTRL_CLR)	32	R/W	0000_4009h	61.5.2/3891
20C_827C	XTAL OSC (LP) Control Register (XTALOSC24M_LOWPWR_CTRL_TOG)	32	R/W	0000_4009h	61.5.2/3891
20C_82A0	XTAL OSC Configuration 0 Register (XTALOSC24M_OSC_CONFIG0)	32	R/W	0000_1020h	61.5.3/3894
20C_82A4	XTAL OSC Configuration 0 Register (XTALOSC24M_OSC_CONFIG0_SET)	32	R/W	0000_1020h	61.5.3/3894
20C_82A8	XTAL OSC Configuration 0 Register (XTALOSC24M_OSC_CONFIG0_CLR)	32	R/W	0000_1020h	61.5.3/3894
20C_82AC	XTAL OSC Configuration 0 Register (XTALOSC24M_OSC_CONFIG0_TOG)	32	R/W	0000_1020h	61.5.3/3894

Table continues on the next page...

XTALOSC24M memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
20C_82B0	XTAL OSC Configuration 1 Register (XTALOSC24M_OSC_CONFIG1)	32	R/W	0000_02EEh	61.5.4/3895
20C_82B4	XTAL OSC Configuration 1 Register (XTALOSC24M_OSC_CONFIG1_SET)	32	R/W	0000_02EEh	61.5.4/3895
20C_82B8	XTAL OSC Configuration 1 Register (XTALOSC24M_OSC_CONFIG1_CLR)	32	R/W	0000_02EEh	61.5.4/3895
20C_82BC	XTAL OSC Configuration 1 Register (XTALOSC24M_OSC_CONFIG1_TOG)	32	R/W	0000_02EEh	61.5.4/3895
20C_82C0	XTAL OSC Configuration 2 Register (XTALOSC24M_OSC_CONFIG2)	32	R/W	0001_02E2h	61.5.5/3896
20C_82C4	XTAL OSC Configuration 2 Register (XTALOSC24M_OSC_CONFIG2_SET)	32	R/W	0001_02E2h	61.5.5/3896
20C_82C8	XTAL OSC Configuration 2 Register (XTALOSC24M_OSC_CONFIG2_CLR)	32	R/W	0001_02E2h	61.5.5/3896
20C_82CC	XTAL OSC Configuration 2 Register (XTALOSC24M_OSC_CONFIG2_TOG)	32	R/W	0001_02E2h	61.5.5/3896

61.5.1 Miscellaneous Register 0 (XTALOSC24M_MISC0)

This register defines the control and status bits for miscellaneous analog blocks.

Address: 20C_8000h base + 150h offset = 20C_8150h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

XTALOSC24M_MISC0 field descriptions

Field	Description
31 VID_PLL_ PREDIV	Predivider for the source clock of the PLL's. NOTE: Not related to oscillator. 0 Divide by 1 1 Divide by 2
30 XTAL_24M_PWD	This field powers down the 24M crystal oscillator if set true.
29 RTC_XTAL_ SOURCE	This field indicates which chip source is being used for the rtc clock. 0 Internal ring oscillator 1 RTC_XTAL
28–26 CLKGATE_ DELAY	This field specifies the delay between powering up the XTAL 24MHz clock and releasing the clock to the digital logic inside the analog block. NOTE: Do not change the field during a low power event. This is not a field that the user would normally need to modify. 000 0.5ms 001 1.0ms 010 2.0ms 011 3.0ms 100 4.0ms 101 5.0ms 110 6.0ms 111 7.0ms
25 CLKGATE_CTRL	This bit allows disabling the clock gate (always ungated) for the xtal 24MHz clock that clocks the digital logic in the analog block. NOTE: Do not change the field during a low power event. This is not a field that the user would normally need to modify. 0 ALLOW_AUTO_GATE — Allow the logic to automatically gate the clock when the XTAL is powered down. 1 NO_AUTO_GATE — Prevent the logic from ever gating off the clock.
24–17 -	This field is reserved. Always set to zero.
16 OSC_XTALOK_ EN	This bit enables the detector that signals when the 24MHz crystal oscillator is stable.
15 OSC_XTALOK	Status bit that signals that the output of the 24-MHz crystal oscillator is stable. Generated from a timer and active detection of the actual frequency.
14–13 OSC_I	This field determines the bias current in the 24MHz oscillator. The aim is to start up with the highest bias current, which can be decreased after startup if it is determined to be acceptable. 00 NOMINAL — Nominal 01 MINUS_12_5_PERCENT — Decrease current by 12.5% 10 MINUS_25_PERCENT — Decrease current by 25.0% 11 MINUS_37_5_PERCENT — Decrease current by 37.5%

Table continues on the next page...

XTALOSC24M_MISC0 field descriptions (continued)

Field	Description
12 DISCON_HIGH_ SNVS	This bit controls a switch from VDD_HIGH_IN to VDD_SNVS_IN. 0 Turn on the switch 1 Turn off the switch
11-10 STOP_MODE_ CONFIG	Configure the analog behavior in stop mode. NOTE: Not related to oscillator. 00 All analog except rtc powered down on stop mode assertion. XtalOsc=on, RCOsc=off; 01 Certain analog functions such as certain regulators left up. XtalOsc=on, RCOsc=off; 10 XtalOsc=off, RCOsc=on, Old BG=on, New BG=off. 11 XtalOsc=off, RCOsc=on, Old BG=off, New BG=on.
9-8 -	This field is reserved. Reserved
7 REFTOP_ VBGUP	Status bit that signals the analog bandgap voltage is up and stable. 1 - Stable. NOTE: Not related to oscillator.
6-4 REFTOP_ VBGADJ	NOTE: Not related to oscillator. 000 Nominal VBG 001 VBG+0.78% 010 VBG+1.56% 011 VBG+2.34% 100 VBG-0.78% 101 VBG-1.56% 110 VBG-2.34% 111 VBG-3.12%
3 REFTOP_ SELFBIASOFF	Control bit to disable the self-bias circuit in the analog bandgap. The self-bias circuit is used by the bandgap during startup. This bit should be set after the bandgap has stabilized and is necessary for best noise performance of analog blocks using the outputs of the bandgap. NOTE: Value should be returned to zero before removing vddhigh_in or asserting bit 0 of this register (REFTOP_PWD) to assure proper restart of the circuit. NOTE: Not related to oscillator. 0 Uses coarse bias currents for startup 1 Uses bandgap-based bias currents for best performance.
2-1 -	This field is reserved.
0 REFTOP_PWD	Control bit to power-down the analog bandgap reference circuitry. NOTE: A note of caution, the bandgap is necessary for correct operation of most of the LDO, pll, and other analog functions on the die. NOTE: Not related to oscillator.

61.5.2 XTAL OSC (LP) Control Register (XTALOSC24M_LOW_PWR_CTRLn)

This register defines xtal osc and low power configuration.

Address: 20C_8000h base + 270h offset + (4d × i), where i=0d to 3d

XTALOSC 24MHz Memory Map/Register Definition

XTALOSC24M_LOWPWR_CTRLn field descriptions

Field	Description
31–19 -	This field is reserved.
18 -	This field is reserved.
17 MIX_PWRGATE	Display power gate control. Used as software mask. Set to zero to force ungated.
16 XTALOSC_PWRUP_STAT	Status of the 24MHz xtal oscillator. 0 Not stable 1 Stable and ready to use
15–14 XTALOSC_PWRUP_DELAY	Specifies the time delay between when the 24MHz xtal is powered up until it is stable and ready to use. 00 0.25ms 01 0.5ms 10 1ms 11 2ms
13 RCOSC_CG_OVERRIDE	For debug purposes only. This bit effects clock gating of certain digital logic clocked by the 24MHz clk.
12 -	Reserved
11 DISPLAY_PWRGATE	Display logic power gate control. Used as software override. NOTE: Not related to oscillator.
10 CPU_PWRGATE	CPU power gate control. Used as software override.

Table continues on the next page...

XTALOSC24M_LOWPWR_CTRLn field descriptions (continued)

Field	Description
	<p>Attention: Test purpose only</p> <p>NOTE: Not related to oscillator.</p>
9 L2_PWRGATE	<p>L2 power gate control. Used as software override.</p> <p>NOTE: Not related to oscillator.</p>
8 L1_PWRGATE	<p>L1 power gate control. Used as software override.</p> <p>NOTE: Not related to oscillator.</p>
7 REFTOP_IBIAS_ OFF	<p>Low power reftop ibias disable.</p> <p>NOTE: Not related to oscillator.</p>
6 LPBG_TEST	<p>Low power bandgap test bit.</p> <p>NOTE: Not related to oscillator.</p>
5 LPBG_SEL	<p>Bandgap select.</p> <p>NOTE: Not related to oscillator.</p> <p>0 Normal power bandgap 1 Low power bandgap</p>
4 OSC_SEL	<p>Select the source for the 24MHz clock.</p> <p>0 XTAL OSC 1 RC OSC</p>
3-1 RC_OSC_PROG	<p>RC osc. tuning values.</p>
0 RC_OSC_EN	<p>RC Osc. enable control.</p> <p>0 Use XTAL OSC to source the 24MHz clock 1 Use RC OSC</p>

61.5.3 XTAL OSC Configuration 0 Register (XTALOSC24M_OSC_CONFIG0n)

This register is used to configure the 24MHz RC oscillator.

Address: 20C_8000h base + 2A0h offset + (4d × i), where i=0d to 3d

XTALOSC24M_OSC_CONFIG0n field descriptions

Field	Description
31–24 RC_OSC_PROG_CUR	The current tuning value in use.
23–20 -	Reserved.
19–16 HYST_MINUS	Negative hysteresis value. Subtracted from target value before comparison. This, along with HYST_PLUS creates a range.
15–12 HYST_PLUS	Positive hysteresis value. Added to target value before comparison. This, along with HYST_MINUS creates a range.
11–4 RC_OSC_PROG	RC osc. tuning values.
3 INVERT	Invert the stepping of the calculated RC tuning value.

Table continues on the next page...

XTALOSC24M_OSC_CONFIG0n field descriptions (continued)

Field	Description
2 BYPASS	Bypasses any calculated RC tuning value and uses the programmed register value.
1 ENABLE	Enables the tuning logic to calculate new RC tuning values. Disabling essentially freezes the state of the calculation.
0 START	Start/stop bit for the RC tuning calculation logic. If stopped the tuning logic is reset.

61.5.4 XTAL OSC Configuration 1 Register (XTALOSC24M_OSC_CONFIG1n)

This register is used to configure the 24MHz RC oscillator.

Address: 20C_8000h base + 2B0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	COUNT_RC_CUR												-				COUNT_RC_TRG															
W	0												0				0															
Reset	0												0				0															

XTALOSC24M_OSC_CONFIG1n field descriptions

Field	Description
31–20 COUNT_RC_CUR	The current tuning value in use.
19–12 -	Reserved
COUNT_RC_TRG	The target count used to tune the RC OSC frequency. Essentially the number of desired RC Osc clock cycles within 1 32KHz clock cycle.

61.5.5 XTAL OSC Configuration 2 Register (XTALOSC24M_OSC_CONFIG2n)

This register is used to configure the 24MHz RC oscillator.

Address: 20C_8000h base + 2C0h offset + (4d × i), where i=0d to 3d

XTALOSC24M_OSC_CONFIG2n field descriptions

Field	Description
31 CLK_1M_ERR_FL	Flag indicates that the count_1m count wasn't reached within 1 32KHz period. This is intended as feedback to software that the HW_ANADIG_OSC_CONFIG2_COUNT_1M_TRG value is too high for the RC Osc frequency.
30-18 -	Reserved.
17 MUX_1M	Mux the corrected or uncorrected 1MHz clock to the output.

Table continues on the next page...

XTALOSC24M_OSC_CONFIG2n field descriptions (continued)

Field	Description
16 ENABLE_1M	Enable the 1MHz clock output. 0 - disabled; 1 - enabled.
15-12 -	Reserved
COUNT_1M_ TRG	The target count used to tune the RC OSC frequency. Essentially the number of desired RC Osc clock cycles within 1 32KHz clock cycles.
